*"I've heard it said that people come into our lives for a reason, bringing something we must learn. And we are led to those who help us most to grow, if we let them and we help them in return. Well, I don't know if I believe that's true, but I know I'm who I am today because I knew you... I have been changed **For Good.**"*

Glinda, The Good — Wicked, Broadway Musical

*Dedico toda a inspiração, esforços, flores e frutos desse trabalho ao meu amado vovozinho, **Jorge Felice Pellegrini**, que partiu antes do começo desta minha jornada, mas me acompanhou antes e ainda me acompanha em sentimento, todos os dias. Obrigado por ter sido essa pessoa tão maravilhosa que você sempre foi; por acreditar e incentivar todos os meus sonhos, por todas as bibliografias cedidas, as discussões taxonômicas que tivemos, por sempre ler de maneira crítica todos os meus manuscritos, por me ajudar com o latim, o francês e os epítetos para as minhas novas espécies, mas principalmente, por ser meu exemplo de vida e inspiração. Tudo o que eu sou e conquistei até hoje é por influência sua. Saudades eternas do seu sorriso carinhoso, seu sotaque italiano e seus olhos azul-celeste.*

AGRADECIMENTOS

Primeiramente, agradeço a todas as pessoas que contribuíram de alguma maneira na realização desse trabalho, mas que a minha memória de peixe-dourado possa vir por não contemplar nos agradecimentos a seguir. Assim, minhas mais sinceras desculpas pelo esquecimento.

À Pós-Graduação em Biodiversidade e Biologia Evolutiva, UFRJ e ao Instituto de Pesquisas Jardim Botânico do Rio de Janeiro, por minha formação e disponibilização de toda a infraestrutura utilizada. A CAPES pela bolsa de estudos concedida.

Aos curadores de todos os herbários visitados ao longo da realização desse projeto e aos curadores de herbários internacionais, que na impossibilidade de enviar materiais em empréstimo, disponibilizaram imagens de altíssima resolução.

Agradeço as minhas maravilhosas orientadoras cítricas, Yin & Yang, **Cassia Mônica Sakuragui** e **Rafaela Campostrini Forzza**. Ambas indispensáveis para a realização e conclusão desse trabalho, contribuindo de maneiras diferentes, ajudando a manter o meu equilíbrio. **Rafa**, muito obrigado por ter me aceitado e acreditado em mim desde a minha iniciação científica, me mantendo no rumo das Commelindas. Obrigado por ser “braba” sempre que necessário, mas sendo sempre uma das pessoas mais amáveis, gentis e carinhosas que já conheci. Obrigado por todos os apelidos, elogios, zoações, risadas e por ser uma das melhores conselheiras que eu tenho. Realmente, não sei se existem palavras que expliquem o quanto importante você foi e é pra mim, e o quanto me conectei com você nesses anos. Obrigado por ser a minha Mamma Italiana botânica! **Cassia**, nossa relação tem uma história complexa, onde comecei sendo seu aluno no bacharelado, depois seu monitor, depois seu “agregado oficial” e finalmente seu orientando. Você sempre me ajudou, me salvou, me orientou, me aconselhou, me amou, e por isso, vejo sempre você como a minha fada-madrinha-botânica, minha fada-verde-*Philodendron*. Obrigado por ser essa pessoa loucamente maravilhosa que alegra tanto a minha vida! Como eu sempre te digo: Lady Araceae, eu sou seu maior fã!

Meus mais sinceros obrigados aos Dr. **Robert B. Faden** (Smithsonian Institution) e Dr. **David R. Hunt** (Royal Botanic Gardens, Kew) por todas as discussões sobre Commelinaceae e todas as inúmeras bibliografias cedidas por ambos. Sem a ajuda de vocês esse trabalho com certeza não teria chegado ao patamar que chegou. Agradeço também ao Dr. **Scott A. Mori** (NYBG), pelos conhecimentos sobre flora neotropical e pelo carinho e interesse pelo meu trabalho. Thank you so much!

Essenciais nessa minha jornada foram os grandes amigos que acumulei ao longo do trajeto. **Luana Silva Braucks Calazans** (a.k.a. Lulu), você foi uma das minhas primeiras amizades na botânica e nossa ridícula relação data desde as monitorias de Vegetais Superiores. Muito obrigado por ser essa amiga esplendorosa, luz total, inteligente como só você consegue ser, e uma companheira para todas as horas. Foram muitos campos, acidentes de trabalho, risadas, comilanças, passeios, piadas e muito, mas muito humor ácido. Você, minha pequena inglesinha, vai ser uma pesquisadora de sucesso, e terei muito orgulho de poder dizer que eu acompanhei esse processo praticamente do começo. Obrigado também por toda ajuda que você me dá, sempre!

Fernanda Santos-Silva (a.k.a. *Honeybum*), você foi um achado na minha vida, a Elphaba da minha Glinda, nós dividimos e vivemos uma infinidade de coisas ao longo desse tempo que nos conhecemos. Foram muitas risadas, felicidades, piadas, humor ácido, momentos filosóficos profundos, *risottos*, brigas, debates e infelizmente muitas lágrimas. Conectei-me com você de uma maneira que é quase impossível de explicar, cuidamos um do outro, mesmo a grandes distâncias. Obrigado por ser a minha parceira no crime sempre, e me socorrer nas filogenias. Que muitos e muitos mais anos de amizade e *papers* ainda estejam por vir e nos unir. **Juliana Amaral de Oliveira** (a.k.a. Julyneide), você chegou quietinha, silenciosa e de maneira bem mineira da salinha, e do mesmo jeito conquistou o meu coração com seus cachinhos e sorriso cativante. Você e sua mistura peculiar de “*hippie-sujisse*” e temperamento *bossy*, fazem de você uma peça chave e especial na minha vida e nesses anos de Salinha. Obrigado por todos os conselhos, puxões de orelhas, beijos, preocupação e amor ao longo dos anos. **Rafael Gomes Barbosa-Silva** (a.k.a. PIBIC), você indubitavelmente é o elemento coração do nosso grupo. Você com esse seu jeito amoroso, sempre sorridente, abraçando e beijando a todos nós todos os dias, foi uma das pessoas que mais contribuiu para que nosso grupo se mantivesse tão unido. Por trás desse sorriso encantador e desse “coraçãozão”, existe um menino genial e trabalhador, que promete um futuro brilhante como pesquisador. Mas você vai ser pra sempre o nosso PIBIC do coração! **Patrícia da Rosa** (a.k.a. Paty), obrigado por ser essa pessoa filosofal, centrada e que em tantos momentos me ajudou a ver o mundo por outra perspectiva. Obrigado pelas comidas vegetarianas, mas especialmente pela risada mais gostosa do mundo! **Rafael Felipe de Almeida** (a.k.a. Mor), meu namorado, que apesar da distância geográfica entre nós, esteve sempre perto e foi um componente crucial dessa dissertação. Muito obrigado por todo o amor, pelo companheirismo, pelo carinho, pelas milhões de risadas, conversas aleatórias pra relaxar

os neurônios, discussões sérias sobre morfologia, sistemática, biogeografia, planos de dominação global, e por ser essa pessoa maravilhosa que se encaixou perfeitamente na minha vida. Obrigado por ser meu porto seguro. Te amo Mor!!!

Ainda, aos outros amigos da Salinha, presente e passado, que foram de grande valia. **Deisy Pereira Saraiva** (a.k.a. Deisoca), a mais bela das “*Pitgatinhas*”, obrigado por me apresentar e aclimatar ao JBRJ, obrigado pela amizade desde os tempos de monitoria de Vegetais Superiores. Saiba que não passa um dia no qual você não faça falta aqui na Salinha e no meu coração. **Herison Medeiros** (a.k.a. Mininu-Herison, Kusama), sou muito grato por ter tido o prazer de conhecer essa pessoa maravilhosa, vinda diretamente do Acre (sim, ele existe). Obrigado por enriquecer taxonômica e culturalmente a minha vida com suas piadas sensacionais, e por ser junto comigo e o Rafael os únicos homens nesse mar de mulheres que é a Salinha dos alunos da Rafa. **Raquel Monteiro**, apesar de sempre reservada e quieta, gostaria de agradecer por tudo que você me ensinou desde que me tornei aluno da Rafa. Meus mais sinceros agradecimentos aos outros colegas passados de Salinha, que tanto ajudaram e ainda ajudam: **Adriana Lobão, Eduardo Leal, Fabiana Filardi, Karina Hmeljevski, Luís Menini Neto, Mariana Saavedra & Paula Leitman.**

Os mais profundos agradecimentos a minha turma original de mestrado pela ENBT, que por razões institucionais não nos permitiu concluir juntos o que começamos. Felizmente, a amizade persistiu e a convivência diária pelos corredores da DIPEQ, almoços, cafés e cervejas nos aproximou ainda mais. Meu amor aos meus queridos: **Alessandra Buccaran, Amélia Tuler, Andrea Tapia, Bruna de Luna, Elisabeth Córdula, Fernanda Masullo, Geissianny Bessão, Leandro Telles, Luana Mauad, Marcus Felippe da Silva, Maria Alice Rezende, Michel Ribeiro, Pablo Viany, Patrícia da Rosa, Simony Colossi & Tainan Messina.** Agradeço ainda a todos os outros amigos que a vivência no JBRJ me proporcionou: **Allan Ribeiro, Ana Raquel Lourenço, Augusto Giaretta, Camila Bonilha, Carolina Potascheff, Cilene de Mattos, Clarisse Martins, Claudio de Fraga, Eline Martins, Elton John de Lírio, Felipe Araújo, James Lucas Costa Lima, João Paulo Condack, Luan Freitas, Luís Fernando da Conceição, Marcio Verdi, Marco Accardo Jr., Nina Pougy, Rafael Felipe de Almeida, Ricardo Couto, Silvana Monteiro, Thiago Meneguzzo & Valderes Sarnaglia Jr..**

Aos meus queridos amigos da UFRJ, PPGBBE e LISV por todo o apoio, conversas, discussões, ajudas no laboratório, disciplinas, cafés, risadas, caronas,

karaokês e bons momentos: **Alessandra Marques, Alexandre Selvatti, Ana Carolina Mezzonato, Anieli Pereira, Annelise Frazão, Antonella Petruzzella, Antônio Solé-Cava, Axel Katz, Carlos Guerra Schrago, Cassia Sakuragui, Cláudia Russo, Daniela Takiya, Dilton Couto Jr., Elisa Costa, Érica Barroso de Moraes, Fernando Ávila, Guilherme Dias, Heber Araújo, Isis Rollim, Karla Reis, Letícia Loss de Oliveira, Livia Bonetti, Lívia Peluso, Lucas Espindola, Marcelo Trovó, Maria Luiza Abieri, Marília Suzy Wängler, Nerivaldo Gomes Antas, Paula Souto, Rafaela Machado, Renata Toledo, Rodrigo Theófilo & Teresa Santos.**

A todos que me acompanharam e me auxiliaram nas minhas viagens, consultas a herbários, coletas e andanças por esse país, que coletaram material de Commelinaceae e me enviaram em duplicatas e para cultivo: **Adriana Lobão, Ana Paula Cardozo, Carla Royer, Daniela Imig, Danilo Gissi, Eduardo Lozano, Luís Funez** (e toda a sua maravilhosa família), **Fernanda Santos-Silva, Greta Aline Dettke, Jaqueline Durigon, João Iganci, Juliana Amaral, Luana Calazans** (e todo o clã Calazans), **Lucia Sevegnani, Marcelo Trovó, Marília Suzy Wängler, Mônica Bolson, Nerivaldo Antas, Paulo Schwirkowski, Rafael Barbosa-Silva, Rafaela Forzza, Rodrigo Theófilo** e tantos outros. Agradecimentos especiais à minha madrinha **Fátima Souza, ao João e ao Lucas** por me abrigarem em São Paulo e em Campinas.

Aos meus amigos não biólogos, que nem por isso contribuíram menos para esse trabalho. Obrigado por me manterem em contato com o meu lado artístico, o meu lado designer, o meu lado de humanas, o meu lado *weirdo*, o meu lado *querky!* Vocês mais do que ninguém foram os que me mantiveram são durante todo esse processo. Um beijo muito grande a esses meus amores de outras vidas, de Petrópolis, de festinhas, de carnavaços, de purpurina, de conversas de bar, de Lapa, ensaios fotográficos, de estúdios e filmagens: **Maíra Barillo, Luiza Gullino, Ísis Daou, Filipe Duarte, Jonia Caon, Fabiana Mimura, Júlio Castro, Jéssica Ocaña, Thomás Agante, William Feijó, Rafael Davila, Luana Lopes, Andressa Martins, Adriana Marchioni, Beatriz Kaippert** e inúmeros outros amores.

Agradeço do fundo do coração a minha ENORME família, que se fosse citada nome por nome ocuparia mais páginas do que se é permito. Cada um de vocês, a sua maneira, contribuiu muito para que esse trabalho fosse realizado e concluído. Em especial, devo agradecer a minha mãe **Ester** pela eterna paciência (e às vezes pela falta da mesma), sempre me incentivando, me mostrando que era possível fazer mais e fazer melhor. Obrigado pelo gene *workaholic!!!* Obrigado ao meu pai, **Mauro**, que apesar de

ser engenheiro, de não sacar nada de plantas, foi um dos meus braços direitos nos mais diversos momentos da minha trajetória acadêmica. Sou muito grato por todas as vezes que você me acompanhou em campo, auxiliou a mim e os mais inúmeros amigos em nossas empreitadas botânicas, sempre com o seu característico “sorriso GE” e um humor peculiar, que acabou por te fazer famoso por toda a botânica brasileira. Aos meus irmãos mais novos, **Conrado e Donato**, que também me acompanharam algumas vezes a campo, mas contribuíram grandemente com o companheirismo em vários momentos de dificuldades profissionais e pessoais. Obrigado também as minhas cunhadas **Rafaela** e **Maria Alice**, por fazerem parte dessa jornada junto com os meus irmãos. Um obrigado especial aos meus avós de ambos os lados, que sempre tiveram um colo quente, um abraço reconfortante e um ombro para acolher as lágrimas que surgiram ao longo do caminho. **Vovó Eunice** e **Vovó Marie**, obrigado por serem as melhores avós que alguém poderia ter. Aos meus avôs **Jorge** e **Otacílio** (ambos *in memoriam*), apesar de termos nos separado antes dessa jornada, vocês me ajudaram como nunca conseguirão imaginar. Vocês dois foram minha fontes de bondade, perseverança e “maravilhamento” pelo mundo. Beijos saudosos do neto que tanto ama vocês! Agradeço a todos os meus tios, em especial ao meu padrinho **Marco Vinicius**, pelo apoio e brincadeiras sempre. Às minhas amadas e queridas tias, pois como diz Cláisse Falcão: “se não fossem as minhas tias com todos os mimos, ou se eu menino fosse mais amado, se não desse errado, não seria eu”. À minha tia **Roberta** (*in memoriam*), saiba que a cada flor que encontro me lembro de você, e que a cada música da Whitney Houston canto e danço pensando em você. Muito obrigado por ter sido a minha irmã mais velha, amiga e conselheira!

Apesar fazerem de parte da família, essas pessoas merecem um parágrafo especial. Obrigado a todos os meus milhões de primos, que são como irmãos mim. Vocês sempre serão parte inseparável de mim! Em especial as minhas primas, as irmãs que eu nunca tive; amor maior vai ser difícil de encontrar. Obrigado por compreenderem a distância e sempre estarem ao meu lado. A minha, mais do que amada afilhada, **Robertinha** (a.k.a. Betinha, Robertossaura), você, minha flor, ainda vai demorar um pouco pra poder ler isso, mas saiba que você com toda a sua alegria, inteligência, inocência e sorriso encantador, ajudou o Dindo nos momentos mais difíceis da vida dele. Obrigado por ser a melhor coisa que já aconteceu na minha vida e sempre recuperar a minha fé na humanidade. O Dindo te ama demais, gordinha!!!

RESUMO

Tradescantia L. pertencente à Commelinaceae (Commelinales) e compreende cerca de 80 espécies de distribuição exclusiva na região Neotropical, sendo o segundo maior gênero da família e membro do clado Neotropical de Tradescantieae. Apesar de vários aspectos de *Tradescantia* já terem sido amplamente estudados (e.g. anatomia, citologia, fitoquímica e palinologia) dados sobre a taxonomia e a filogenia do grupo ainda são pouco abordados. O presente trabalho teve como objetivo apresentar um estudo sistemático sobre o gênero, focando em *Tradescantia* sect. *Austrotradescantia*. O Capítulo 1 apresenta a taxonomia das espécies de *Tradescantia* descritas por Frei Mariano Conceição Vellozo na sua obra *Flora fluminensis*, com comentários para as espécies brasileiras do gênero. O Capítulo 2 aborda o problema taxonômico que circunda o nome *Tradescantia cymbispatha*, indicando sua identidade e aplicação. Nesse mesmo trabalho são designados dois lectótipos e é descrita uma nova espécie, *Tradescantia praetermissa*. O Capítulo 3 apresenta a revisão taxonômica de *Tradescantia* sect. *Austrotradescantia*, com base em extensos trabalhos de campo, análises de materiais de herbários nacionais e internacionais e todas as obras originais relacionadas ao grupo. *Tradescantia* sect. *Austrotradescantia* apresenta 10 espécies restritas a América do Sul, tendo como sinapomorfias morfológicas o estigma punctiforme e os estames iguais entre si, densamente barbados com longos tricomas moniliformes na porção basal. Das 10 espécies reconhecidas, duas são novas para a ciência, duas são incluídas na seção e duas são nomes reestabelecidos. Ainda, é designado um total de sete lectótipos e um epítipo. Nesse capítulo também é apresentada uma hipótese filogenética para *Tradescantia* seção *Austrotradescantia*, feita com base em caracteres morfológicos, citogenéticos e fitoquímicos.

Palavras-chave: Filogenia; nomenclatura; taxonomia; Thyrsantheminae; Tradescantiinae; trapoeraba

ABSTRACT

Tradescantia L. is the second largest genus of Commelinaceae (Commelinales), which possess an exclusively Neotropical distribution and *circa de* 80 species and a member of the Neotropical clade of Tradescantieae. Although many aspects of *Tradescantia* such as anatomy, cytology, chemistry and palynology have been widely studied and well known, data on its systematics are still scant. The current work aims to present a more profound systematic study on the genus, focusing in *Tradescantia* sect. *Austrotradescantia*. Chapter 1 presents the taxonomy of *Tradescantia* names described by Friar Mariano Conceição Vellozo in his *Flora fluminensis*, with comments in the Brazilian species of the genus. Chapter 2 solves the taxonomic problem involving the name *Tradescantia cymbispatha*, indicating its identity and application. In the same work, two lectotypes are designated and a neglected new species, *Tradescantia praetermissa*, is described. Finally, Chapter 3 presents the taxonomic revision of *Tradescantia* sect. *Austrotradescantia*, based on extensive field, herbaria and bibliographical work. *Tradescantia* sect. *Austrotradescantia* comprises 10 species restricted to South America, having as morphological synapomorphies the punctate stigma and the equal stamens, densely bearded with long moniliform hairs in the basal portion of the filament. Also in this chapter, a phylogenetic hypothesis for *Tradescantia* section *Austrotradescantia* is presented based on morphological, cytological and phytochemical characters.

Key words: Nomenclature; phylogeny; taxonomy; Thysantheinae; Tradescantiinae; wandering Jew

INTRODUÇÃO GERAL

A região Neotropical é provavelmente a mais biodiversa do mundo e abriga um total estimado de 90.000–110.00 espécies de plantas com sementes; um número provavelmente maior que o total de espécies da África tropical, Ásia tropical e Oceania combinados (Antonelli & Sanmartín 2011). Esta foi definida por De Candolle (1820) como incluindo desde o México, passando pela América Central, até a América do Sul. Como já apontado por diversos autores (e.g. Antonelli & Sanmartín 2011, Condon *et al.* 2008, Calazans *et al.* 2014), informação filogenética em diferentes grupos de organismos se mostra de suma importância para um melhor entendimento da história biogeográfica e da diversidade da região Neotropical.

Commelinaceae é uma família de monocotiledôneas com distribuição predominante nas regiões tropicais e subtropicais do mundo (Faden 1998), tendo a região Neotropical como um dos seus centros de diversidade, devido ao grande número de representantes das subtribos *Tradescantiinae* e *Dichorisandrinae* (Hunt 1994; Hardy 2001; Aona 2008). A família pertencente à ordem *Commelinales* (APG 2009), sendo composta por 41 gêneros e aproximadamente 670 espécies (The Plant List 2013). A morfologia da família é bastante variável, abrangendo desde ervas diminutas [e.g. *Callisia* *filliformis* (M.Martens & Galeotti) D.R.Hunt], a ervas robustas [e.g. *Dichorisandra* *thyrsiflora* J.C.Mikan] a trepadeiras [e.g. *Dichorisandra* *hexandra* (Aubl.) C.B.Clarke]. As *Commelinaceae* são plantas suculentas, com folhas alternodísticas ou espiraladas, margens inteiras e bainhas fechadas. Células com mucilagem são frequentes e a presença de canais de ráfides é a sinapomorfia morfológica da família. As inflorescências são tirsóides formadas por 1–vários cincos livres ou fusionados, sésseis ou pedunculados, dispostos de maneira verticilada, oposta ou alterna; reduções são bastante comuns nas estruturas de inflorescências e sínflorescências. As flores são efêmeras com corolas trímeras, deliquescentes e tornam *Commelinaceae* uma das famílias mais difíceis de serem estudadas com base em material herborizado. Geralmente apresentam grande especialização no androceu que pode variar de (1–)3–5–6 estames, dispostos em duas séries, nas flores masculinas ou hermafroditas, com 1–4 estaminódios ou suprimidos em diferentes gêneros, anteras com conectivos expandidos ou contraídos, e anteras de deiscência rimosa, poricida ou ainda rimosa, mas funcionalmente poricida. O gineceu é sempre súpero, 3-carpelar, mas a aborção de um ou mais lóculos são comuns em espécies de inúmeros gêneros (e.g. *Aneilema* R.Br.,

Commelina L.) ou caracterizam gêneros inteiros (e.g. *Floscopia* Lour.). Os frutos são cápsulas 2–3-valvadas, raro frutos secos indeiscentes, mais raro ainda bagas, as sementes possuem uma caliptra que fica posicionada sobre o embrião e é denominada embrioteca; a posição dessa estrutura se mostra de grande relevância taxonômica (Faden 1985; Faden 1991; Faden 1998; Panigo *et al.* 2010). A família é economicamente importante devido ao valor ornamental de inúmeros gêneros e pelo grande número de espécies invasoras, especialmente nos gêneros *Commelina* e *Tradescantia* L. (Hunt 2001; Burns 2008).

Atualmente Commelinaceae encontra-se dividida em duas subfamílias corroboradas por dados morfológicos e moleculares (Faden & Hunt 1991, Evans *et al.* 2003, Burns *et al.* 2011): Cartonematoideae e Commelinoideae (Fig. 1). Entretanto, estudos moleculares ainda são necessários para definir melhor os limites entre as subfamílias e tribos, já que a posição da subtribo Palisotinae ainda é incerta. *Palisota* Rchb., o único gênero da subtribo, é ora recuperado como grupo-irmão do restante da subfamília Commelinoideae (Evans *et al.* 2003) ou como grupo-irmão da tribo Commelineae (Burns *et al.* 2011). Cartonematoideae é restrita a Ásia, Austrália e África, e é representada por dois gêneros e cerca de 15 espécies (Faden 1998). Commelinoideae abrange a maior diversidade da família, com 39 gêneros, e distribuição predominantemente tropical e subtropical, sendo definida pela presença de canais de ráfides nunca próximos às nervuras foliares e pela presença de microtricomas glandulares. A subfamília é divida em duas tribos Commelineae e Tradescantieae, a última sendo parafilética (Faden & Hunt 1991; Evans *et al.* 2003) (Fig. 1). Commelineae é caracterizada por apresentar estômatos com seis células subsidiárias onde o par terminal é menor que o segundo par lateral, os grãos de pólen apresentam exina espinulosa e teto perforado, flores predominantemente zigomorfas e tricomas nos filamentos (quando presentes) geralmente não moniliformes (Faden & Hunt 1991).

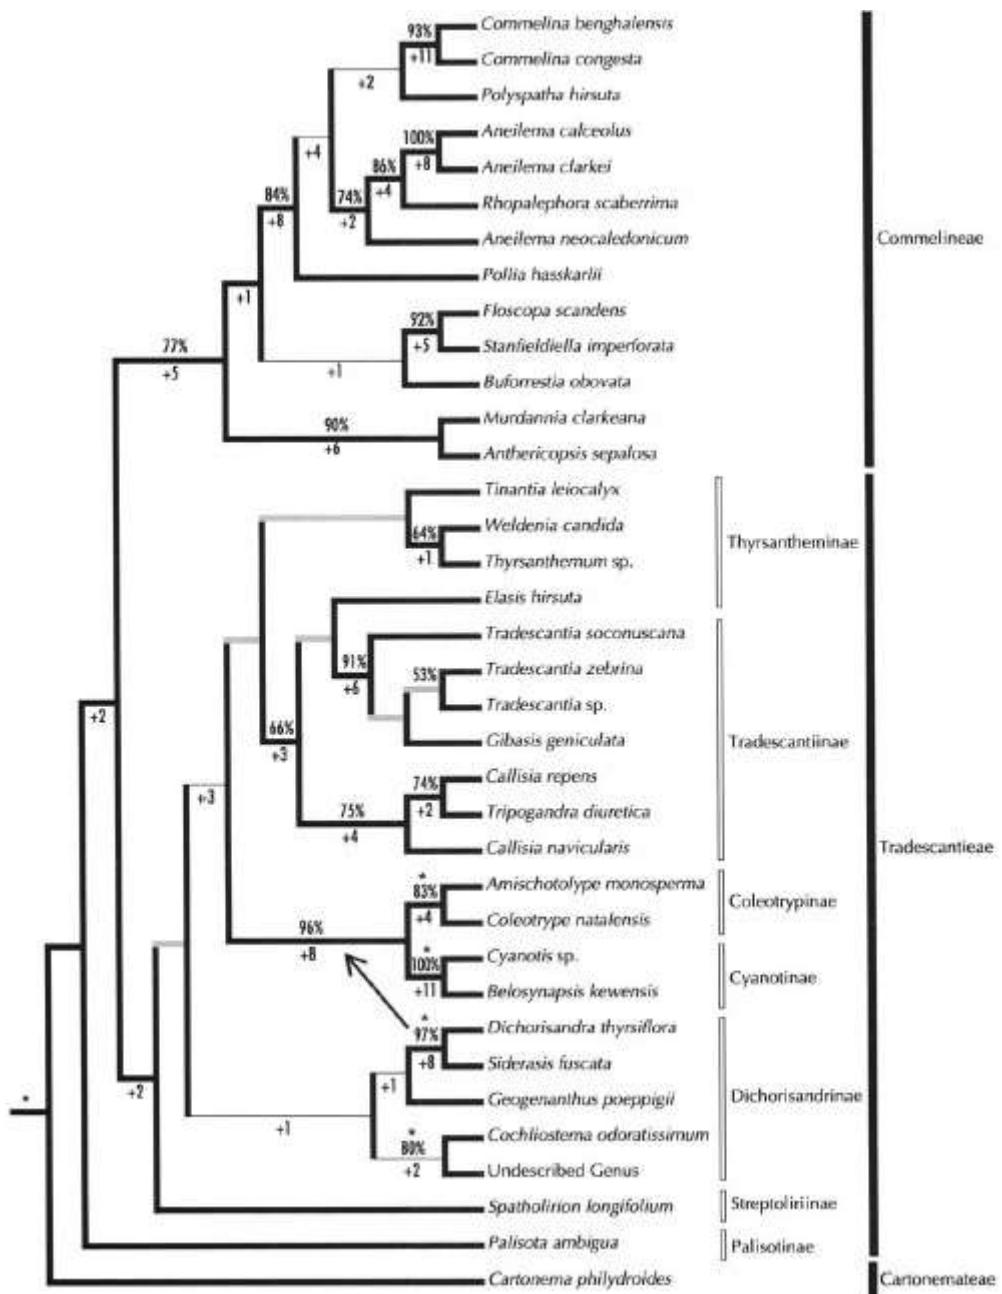

Figura 1. Árvore filogenética da família Commelinaceae resultante da análise combinada do gene plastidial *rbcL* e dados morfológicos (modificado de Evans *et al.* 2003).

A tribo Tradescantieae é caracterizada por apresentar estômatos com duas a quatro células subsidiárias, quando seis, o par terminal maior ou igual ao par lateral, os grãos de pólen apresentam exina insular-cerebroide e teto não-perforado, flores predominantemente actinomorfas e tricomas moniliformes nos filetes (Faden & Hunt 1991). Em sua atual circunscrição (Faden & Hunt 1991), a tribo é dividida em sete subtribos, sendo recuperada como parafilética, devido à posição de *Palisotinae*. A tribo tem sido foco de grande parte dos trabalhos sistemáticos na família, com vários gêneros revisados ou descritos recentemente (e.g. *Dichorisandra*, *Gibasis* Raf., *Plowmanianthus*

Hardy & Faden, *Tripogandra* Raf.; Aona 2008, Hunt 1986a, Hardy & Faden 2004, Handlos 1975, respectivamente). Ainda nesta tribo, grande parte dos esforços se concentrou em tentar organizar gêneros taxonomicamente complexos, como *Tradescantia* e *Callisia* Loefl. (Hunt 1975, 1980, 1986b, 1986c, respectivamente). As subtribos Tradescantiinae e Thyrsantheminae formam um clado exclusivamente Neotropical (Wade *et al.* 2006), chamado de “Complexo *Tradescantia*” por Woodson (1942) e “Aliança *Tradescantia*” por Hertweck & Pires (2014). Ambas as tribos são

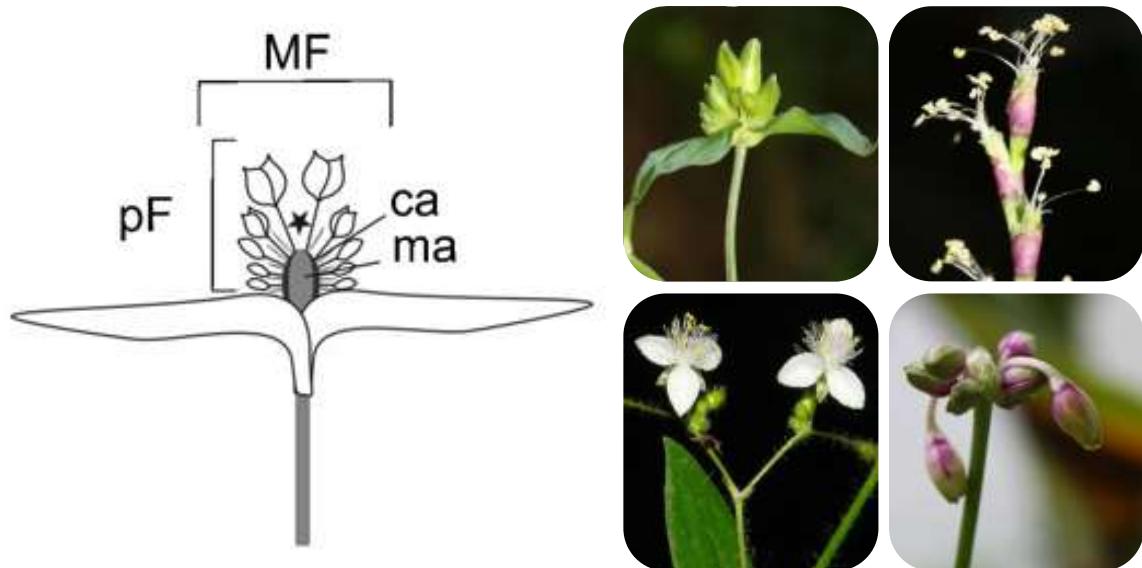

Figura 2. Inflorescência característica da subtribo Tradescantiinae, chamada de duplo cincinno dorsalmente fusionado. **MF**= Florescência principal; **pF**= Florescência parcial; **ma**= eixo principal; **ca**= eixo do cincinno. Começando da esquerda superior, em sentido horário, estão representantes dos quatro gêneros atualmente aceitos em Tradescantiinae: *Tradescantia*, *Callisia*, *Tripogandra* e *Gibasis*. Modificado de Panigo *et al.* 2010.

recuperadas como parafiléticas em todos os trabalhos de filogenia realizados até o momento (Evans *et al.* 2000, Evans *et al.* 2003, Wade *et al.* 2006, Burns *et al.* 2011, Hertweck & Pires 2014). Entretanto, nenhuma posição taxonômica sobre a circunscrição das mesmas foi tomada, sendo ainda aceita a circunscrição originalmente proposta por Faden & Hunt (1991).

Tradescantiinae (*sensu* Faden & Hunt 1991) é composta pelos gêneros *Callisia*, *Gibasis*, *Tradescantia* e *Tripogandra*. A subtribo é caracterizada pelas suas florescências principais, que consistem de um tirso reduzido a apenas dois cincinos, fusionados dorsalmente, ou por dois a vários cincinos estipitados e geniculados organizados em um tirso umbelado (Faden & Hunt 1991; Panigo *et al.* 2010) (Fig. 2). Os cincinos são geralmente contraídos, em oposição aos cincinos alongados da subtribo Thyrsantheminae, com a exceção mais marcante sendo *Callisia warszewicziana* (Kunth

& Bouché) D.R.Hunt, que possui cincinios alongados e parcialmente fusionados (Faden & Hunt 1991). Ambas as subtribos vem sendo recuperadas como parafiléticas em todos os estudos filogenéticos, utilizando tanto dados moleculares quanto dados morfológicos, devido à inclusão de *Elasis* D.R.Hunt em *Tradescantiinae* (e.g. Evans *et al.* 2000; Evans *et al.* 2003; Wade *et al.* 2006; Hertweck & Pires 2014). A subtribo *Thyrsantheminae* não apresenta sinapomorfias morfológicas e representa um agrupamento heterogêneo de gêneros pequenos ou monoespecíficos (obs. pess.).

Tradescantia, em sua circunscrição atual, é o segundo maior gênero da família com ca. 80 espécies e uma distribuição natural exclusivamente neotropical (Faden 1998; eMonocot 2010; The Plant List 2013). A última revisão taxonômica para o grupo foi realizada por Clarke (1881), que reconheceu 36 espécies organizadas em três seções. Duas das seções reconhecidas por Clarke (1881) atualmente são tratadas como gênero: *Descantaria*, caracterizada pelos estames dimorfos, hoje corresponde ao gênero *Tripogandra* (Handlos 1975); e *Monantha*, caracterizada pelas inflorescências unifloras axilares hoje corresponde ao gênero *Matudanthus* D.R.Hunt (Hunt 1978). A terceira seção, *Eutradescantia*, caracterizada por apresentar seis estames iguais ou subiguais, continha representantes atualmente posicionados em: *Callisia*, *Elasis*, *Gibasis*, *Gibasoides* D.R.Hunt e *Tradescantia sensu* Hunt (1980).

Com base em seus estudos sinópticos sobre a tribo *Tradescantieae*, Hunt (1975, 1980, 1986b) propôs uma nova classificação infragenérica para *Tradescantia*, que passou a abrigar 12 seções e quatro séries (subordinadas a uma mesma seção). Grande parte das seções estabelecidas por este autor representavam gêneros tradicionalmente segregados de *Tradescantia* como: *Campelia* Rich., *Cymbispatha* Pichon, *Mandonia* Hassk. *nom. illeg.*, *Rhoeo* Hance, *Setcreasea* K.Schum. & Sydow, e *Zebrina* Schnizl. Fora isso, outras seções propostas representam complexos de espécies tradicionalmente reconhecidos por outros autores, como o complexo *T. fluminensis* Vell. (Woodson 1942) e o complexo *T. virginiana* L. (Anderson & Woodson 1935). Essa classificação é a atualmente aceita para o gênero, apesar de metade das seções propostas serem monoespecíficas (i.e. *Campelia*, *Coholomia*, *Parasetcreasea*, *Rhoeo*, *Separotheca* e *Zebrina*), o que se mostra pouco prático do ponto de vista sistemático.

Recentemente duas filogenias utilizando caracteres moleculares (Burns *et al.* 2011; Hertweck & Pires 2014) abordaram a classificação infragenérica proposta for-

Hunt (1975, 1980, 1986b). Burns *et al.* (2011) apresentaram uma filogenia para a subfamília Commelinoidae e focaram a sua amostragem nos dois maiores gêneros da família, *Commelina* e *Tradescantia*, com o intuito de testar suas classificações infragenéricas. Esse trabalho teve representantes de nove das 12 seções e três das quatro séries propostas por Hunt (1975, 1980, 1986b), com uma pequena parcela das espécies do grupo (apenas 18 das ca. 80 espécies) e poucas espécies *typus* amostradas. O trabalho de Hertweck & Pires (2014) dispôs de uma amostragem bem mais ampla (30 de ca. 80 espécies), contando com algumas seções previamente não amostradas, porém manteve uma lacuna referente às espécies *typus* das seções e séries. Apesar da grande diferença amostral entre os trabalhos, a topologia recuperada é bastante congruente. Desconsiderando as seções monoespecíficas (i.e. 50% delas), apenas duas seções são consistentemente recuperadas como monofiléticas (i.e. *Austrotradescantia* e *Setcreasea*), dessas *Austrotradescantia* sempre com suporte elevado (BS= 84/ PP= 100, Burns *et al.* 2011; BS= 100, Hertweck & Pires 2014). Além disso, a seção apresenta características fitoquímicas (Martínez & Martínez 1993), citológicas (Jones & Jopling 1972) e morfológicas (Owens 1981) bastante características. *Tradescantia* seção *Austrotradescantia* nunca foi revisada, tendo recebido apenas uma sinopse (Hunt 1980), onde foi apresentado o número estimado de espécies, a distribuição da seção e sua morfologia geral. Esta dissertação se insere nesse contexto, visando preencher essa lacuna de conhecimento sobre o gênero *Tradescantia*, especialmente sobre a seção *Austrotradescantia*.

OBJETIVOS

- Solucionar os problemas nomenclaturais envolvendo os nomes brasileiros de *Tradescantia*;
- Esclarecer os limites morfológicos entre as seções *Austrotradescantia* e *Cymbispatha*;
- Testar o monofiletismo de *Tradescantia* seções *Austrotradescantia* e *Cymbispatha*, e apresentar uma hipótese da sua relação com as seções restantes de *Tradescantia*, com base em caracteres morfológicos;
- Realizar a revisão taxonômica e apresentar a primeira hipótese filogenética para *Tradescantia* seção *Austrotradescantia*;

ORGANIZAÇÃO DA DISSERTAÇÃO

A presente dissertação se encontra dividida em três capítulos que tratam da nomenclatura, taxonomia e filogenia de *Tradescantia* com enfoque na seção *Austrotradescantia*. Cada capítulo é apresentado na forma de artigo seguindo as normas de formatação das revistas onde cada um deles foi ou será submetido. A seguir, apresentamos uma breve sinopse de cada capítulo:

- **CAPÍTULO 1– A nomenclatural and taxonomic review of *Tradescantia* (Commelinaceae) species described in Vellozo's *Flora fluminensis* with notes on Brazilian *Tradescantia*** – Esse capítulo encontra-se publicado na revista Taxon e apresenta uma revisão nomenclatural e taxonômica dos nomes de *Tradescantia* descritos pelo Frei José Mariano da Conceição Vellozo em sua obra *Flora fluminensis*.
- **CAPÍTULO 2– (Con)Fused bracts: The identity and application of *Tradescantia cymbispatha* and a neglected new *Tradescantia* species from Bolivia** – Esse capítulo encontra-se formatado segundo a revista Taxon e trata sobre questão nomenclatural envolvendo o nome *Tradescantia cymbispatha* C.B.Clarke que gerou confusão taxonômica entre *Tradescantia* as seções *Austrotradescantia* e *Cymbispatha*.
- **CAPÍTULO 3– Wandering through South America: Taxonomic revision and phylogeny of *Tradescantia* sect. *Austrotradescantia* (Commelinaceae)** – O Capítulo 3 encontra-se formatado de acordo com a revista Botanical Journal of the Linnean Society e apresenta a revisão taxonômica de *Tradescantia* sect. *Austrotradescantia* D.R.Hunt. Nesse capítulo também é apresentada uma hipótese filogenética *Tradescantia* seção *Austrotradescantia*, feita com base em caracteres morfológicos, citogenéticos e fitoquímicos.

CAPÍTULO 1

A nomenclatural and taxonomic review of *Tradescantia* (Commelinaceae) species described in Vellozo's *Flora fluminensis* with notes on Brazilian *Tradescantia*

DOI <http://dx.doi.org/10.12705/641.3>

Abstract *Tradescantia* names from Vellozo's *Flora fluminensis* are revised, five lectotypes and one epitype are designated; one name is accepted and three names are treated as synonyms. Notes on *Tradescantia* sect. *Austrotadescantia* and *Tradescantia* sect. *Cymbispatha* are presented, based on the studies of Vellozo's names. Also, further notes on the Brazilian *Tradescantia* and a key for the sections occurring in Brazil are here presented.

Keywords *Austrotadescantia*; *Cymbispatha*; Neotropical flora; Rio de Janeiro; *Tradescantiinae*

■ INTRODUCTION

During the 18th century (specifically 1777–1808), the Portuguese Empire conducted several scientific expeditions throughout its world-wide domains, called by historians the “Portuguese Philosophical Travels” (Pataca, 2011). These expeditions were divided and organized based on the political structure of the colonies. The Brazilian territory was covered by two expeditions: a northern one settled in the Amazonian city of Belém, coordinated by Alexandre Rodrigues Ferreira, and a southeastern one in Rio de Janeiro, coordinated by Friar José Mariano da Conceição Vellozo (Damasceno, 1977; Pataca, 2011).

The monumental publication *Flora fluminensis* was the result of Vellozo's expeditions and is the first work on the flora of Brazil that was written and edited by a Brazilian. It includes descriptions and illustrations of 1640 plants, arranged in one volume of descriptions and eleven volumes of plates (Borgmeier, 1961; Carauta, 1973; Cervi & Rodrigues, 2010). Borgmeier (1961) and Carauta (1969) have already discussed the complicated publishing history of this work in great detail. To summarize their discussion, *Flora fluminensis* was completed by Vellozo in 1790, but due to countless political reasons, printing up to page 352 was only completed in 1825 (Borgmeier, 1961; Carauta, 1969, 1973), and the distribution of the work began in 1827 (Carauta, 1973). A complete version of the text was only issued in 1881; in a special issue of the *Archivos do Museu Nacional do Rio de Janeiro* (Borgmeier, 1961; Lima, 1995), edited by Ladislau de Souza Mello-Netto, Director of the Museu Nacional do Rio de Janeiro (Mello-Netto, 1881). The printing of the plates was completed in 1829, but the distribution of the volumes did not occur until 1831

(Carauta, 1973). Nevertheless, two centuries later, most of the names of Commelinaceae described have not been properly reviewed or acknowledged. This is due to the historical difficulty associated with accessing physical copies of the publication, its complicated publishing history, and the overall depreciation of Vellozo's work (Borgmeier, 1961; Carauta, 1969, 1973; Valle, 1985).

As part of the ongoing studies of the revision of *Tradescantia* sect. *Austrotadescantia* D.R.Hunt by the authors, we conducted an extensive review of the Commelinaceae names published by Vellozo. We present the results of this review here together with taxonomical notes on Brazilian *Tradescantia* L. and a key for the Brazilian sections of *Tradescantia*.

■ TYPIFICATION

Many researchers have assumed that Vellozo did not make collections of the plants that he described as new. In fact, Vellozo's original specimens were sent to the Museu Real de Lisboa between 1797 and 1798; where he stayed for a while, organizing the herbarium collection (Borgmeier, 1937). During his stay at the Museu Real de Lisboa, it is probable that he inserted the specimens from his *Flora fluminensis* into the herbarium (Borgmeier, 1937, 1961; Lima, 1995). In addition to the specimens Vellozo placed in Lisboa, Hamy (1908) referred to 246 Vellozo specimens arranged in two separate batches (117 and 129 specimens) that were stated to have arrived in Portugal, with the first batch (consisting of 117 specimens) being sent to Paris (Bocage, 1862). Despite evidence that specimens collected by Vellozo, presumably including types of the names

he introduced, arrived in Europe, nothing is known about the current whereabouts of a single Vellozo specimen. Despite repeated attempts by botanists over many years, no original material has ever been found in Portugal or in Paris (e.g., Lima, 1995; Pastore, 2013). Due to the lack of vouchers, the iconographies have frequently been used by botanists for the purpose of reviewing the taxa described by Vellozo (Carauta, 1969; Mello Filho, 1975; Cervi & Rodrigues, 2010; Buzatto & al., 2013; Pastore, 2013; Aona-Pinheiro & al., 2014).

After a careful analysis of the *Flora fluminensis* we conclude that the illustrations of Commelinaceae presented by Vellozo (1831) are in general accurate, with few being considered inaccurate. According to the *Code* (McNeill & al., 2012: Art. 38.9), illustrations with analysis or diagnosis are eligible as type specimens. Since none of Vellozo's original specimens have been located, and in accordance with the requirements of the *Melbourne Code* (McNeill & al., 2012: Art. 9.3), the illustrations mentioned in the protologue, although published later, are considered to be part of the author's original material. Thus, Vellozo's illustrations are here selected as lectotypes. We have also designated an epitype when the original plate was insufficient to apply a name to a given species with certainty. The species are presented here in the same order as that of Vellozo's *Flora fluminensis* and the accepted names appear in bold.

■ TAXONOMY

1. *Tradescantia capitata* Vell., Fl. Flumin.: 139. 1829, nom. illeg., non Blume 1827 – **Lectotype (designated here):** [illustration] Original parchment plate of *Flora fluminensis* in the Manuscript Section of the Biblioteca Nacional, Rio de Janeiro [cat. no.: mss1198652_155] and later published in Vellozo, Fl. Flumin. Icones 3: t. 151. 1831.

= *Tradescantia zanonia* (L.) Sw., Prodr.: 57. 1788 ≡ *Commelina zanonia* L.

Nomenclatural notes. – Due to the tortuous publishing history of Vellozo's work (Borgmeier, 1961; Carauta, 1969, 1973; Valle, 1985), doubt has arisen regarding whether Blume's or Vellozo's name had priority. Since Vellozo's *Flora fluminensis* was only effectively published in 1829 (Carauta, 1973), *Tradescantia capitata* Vell. is a later homonym of *T. capitata* Blume (= *Belosynapsis ciliata* (Blume) R.S.Rao). Thus Vellozo's name is illegitimate.

Taxonomical notes. – The plate for *Tradescantia capitata* Vell. perfectly illustrates the habit of *T. zanonia*, specifically the indumentum of the leaves (glabrous adaxially and villous to lanate abaxially), the axillary inflorescences breaking through the leaf-sheaths, the capitate stigma, and the capsules covered by the persistent and fleshy sepals. Thus, it is clear that *T. capitata* Vell. is a synonym of *T. zanonia*. This name was already cited as a synonym of *Campelia zanonia* (L.) Kunth (= *Tradescantia zanonia*) by Sampaio & Peckolt (1943).

2. *Tradescantia fluminensis* Vell., Fl. Flumin.: 140. 1829 – **Lectotype (designated here):** [illustration] Original parchment plate of *Flora fluminensis* in the Manuscript

Section of the Biblioteca Nacional, Rio de Janeiro [cat. no.: mss1198652_156] and later published in Vellozo, Fl. Flumin. Icones 3: t. 152. 1831.

Nomenclatural notes. – *Tradescantia fluminensis* is the oldest name for this species and it is the type for *T. sect. Austrotradescantia*. This name is widely used in local Floras and taxonomic studies (e.g., Hunt, 1980; Barreto, 1997; Aona, 2009; Aona & Pellegrini, 2014). In the original description, Vellozo (1829) mentioned some ecological features of the species, including its occurrence in marine-influenced vegetation (restinga), but gave no specific location. Despite many efforts to collect *T. fluminensis* from restinga areas in Rio de Janeiro State have been made, all of these to date have been unsuccessful. The municipality of Paraty was the subject of at least one of Vellozo's expeditions (Borgmeier, 1937; Lima, 1995), and it possesses one of the few areas with well-preserved restinga vegetation in the state of Rio de Janeiro, being most probably the type locality of *T. fluminensis*.

3. *Tradescantia geniculata* Vell., Fl. Flumin.: 140. 1829 (“*geniculata*”), nom. illeg., non Jacq. 1763 ≡ *Cymbispatha geniculata* (Vell.) Pichon in Notul. Syst. (Paris) 12: 224. 1946 – **Lectotype (designated here):** [illustration] Original parchment plate of *Flora fluminensis* in the Manuscript Section of the Biblioteca Nacional of Rio de Janeiro [cat. no.: mss1198652_157] and later published in Vellozo, Fl. Flumin. Icones 3: t. 153. 1831 – **Epitype (designated here):** BRAZIL. Rio de Janeiro, Petrópolis, bairro Castelânea, fl., 8 Aug 2010, M.O.O. Pellegrini 17 (RB No. 595794!; isoepitype: RFA No. 36865!). — For an image of the lectotype, see Fig. 1A–B.

- = *Tradescantia mundula* var. *scabrida* Seub. in Martius, Fl. Bras. 3(1): 249. 1855, **syn. nov.** – **Lectotype (designated here):** BRAZIL. s. loc., s. dat., F. Sellow 3852 (B barcode B 10 0247278!).

Nomenclatural notes. – *Tradescantia geniculata* Vell. (published as *T. giniculata* in the *Icones*, an orthographic variant), the oldest name for this species, unfortunately is rendered illegitimate by the pre-existing *T. geniculata* Jacq. (≡ *Gibasis geniculata* (Jacq.) Rohweder). Although the plate presented by Vellozo for *T. geniculata* (1831: t. 153) is not informative for identification at the species level, it was clear enough to place this taxon in *T. sect. Austrotradescantia*.

There appears to be an historical confusion between *Tradescantia* sect. *Austrotradescantia* and *T. sect. Cymbispatha* (Pichon) D.R.Hunt. The confusion began with Clarke (1881), who described *T. cymbispatha* C.B.Clarke, which had sub-equal stamens (the two whorls being of different lengths), and listed *T. geniculata* Vell. as a synonym of his new species. Later, Pichon (1946) described the genus *Cymbispatha*, and characterized it as possessing inflorescences subtended by two cymbiform (spathe-like), basally fused bracts and seeds with lateral to semi-lateral embryotega. Pichon (1946) placed *T. cymbispatha* within the genus *Cymbispatha*, but to avoid the creation of a tautonym (McNeill & al., 2012: Art. 23.4), combined *T. geniculata* instead, unaware that it was an illegitimate name. Hunt (1980) reduced many of the genera segregated from

Tradescantia to sections of the latter, with *T.* sect. *Cymbispatha* being characterized by possessing inflorescences subtended by two cymbiform (spathaceous), basally fused bracts, sub-equal stamens, linear-sagitate to laterally tapered connective (sometimes the intern angle of the connective so obtuse that it is almost) and seeds with lateral to semi-lateral embryotega.

During the ongoing revision of *Tradescantia* sect. *Austrotradescantia*, it was found that none of the Brazilian *Tradescantia* species showed any of these characters. Vellozo's plate for *T. geniculata* (Vellozo, 1831: t. 153) shows the upper view of an inflorescence (Fig. 1A, white arrow), giving the impression that the bracts are fused, a characteristic of the section

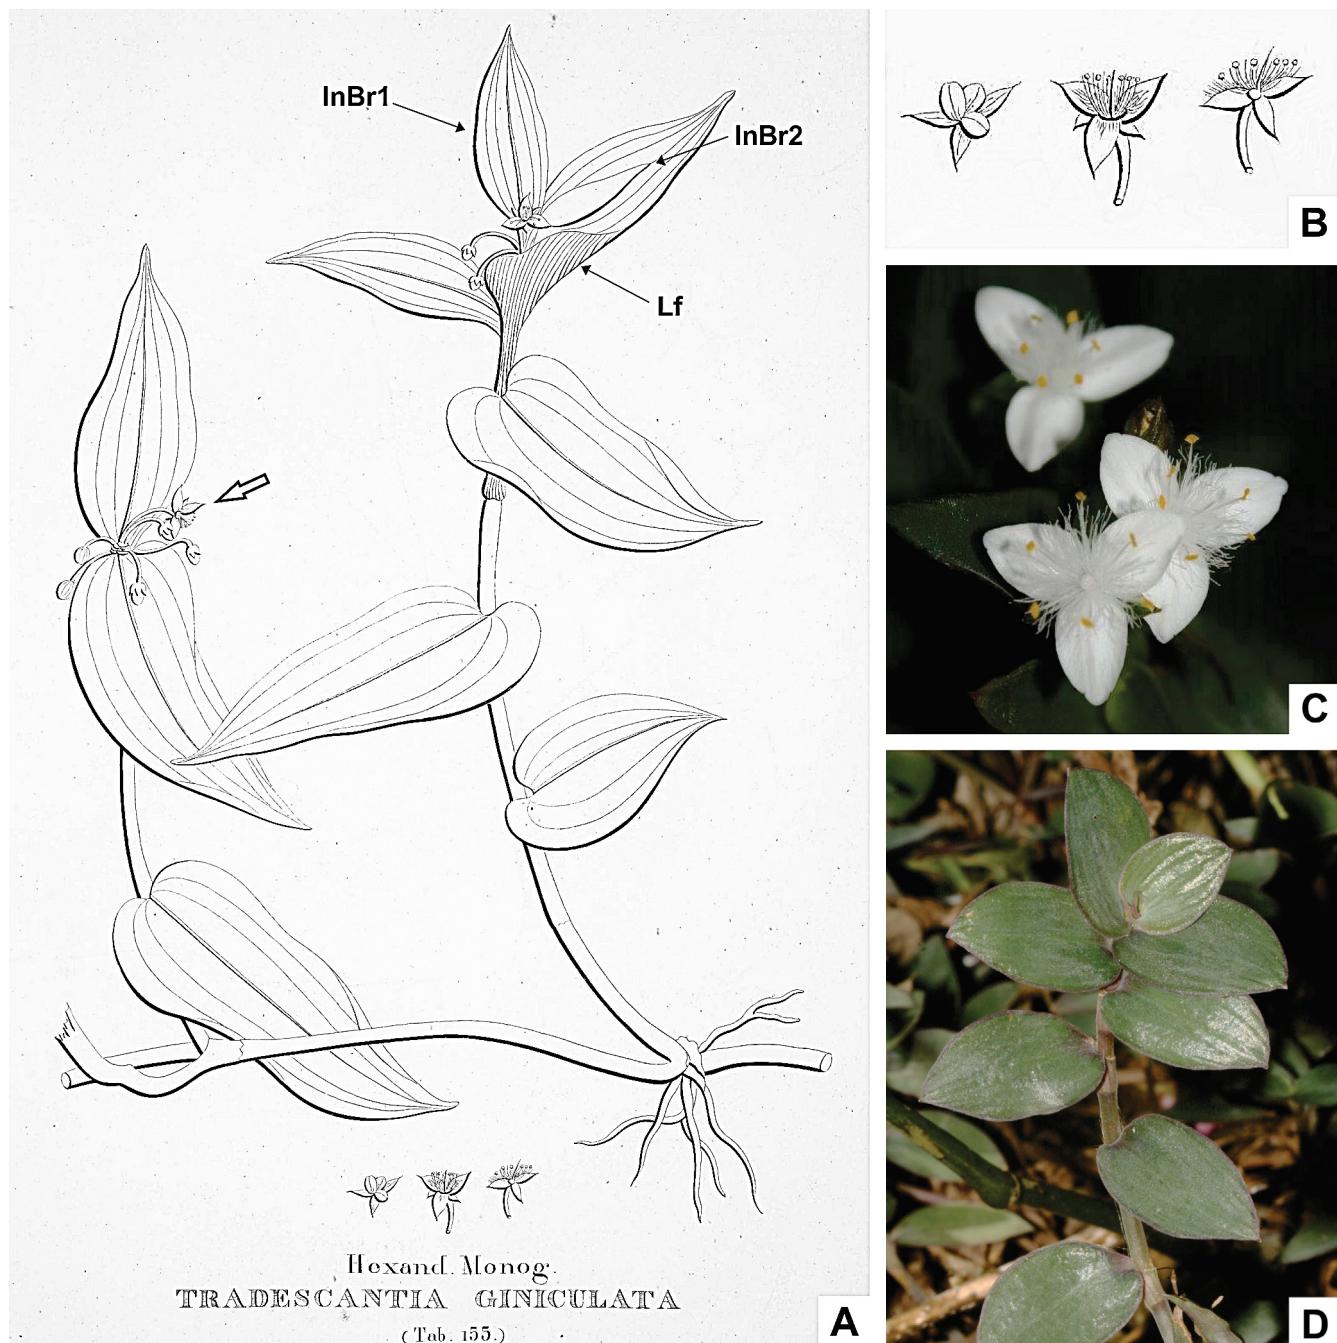

Fig. 1. *Tradescantia geniculata* and *T. mundula* var. *scabrida*. **A–B**, image of the *T. geniculata* plate from the Biodiversity Heritage Library: **A**, line drawings of habit, inflorescence and floral characters (white arrow shows inflorescence seen from above); **B**, detail of floral and fruit characters, showing an open capsule, a complete flower and a flower with dissected corolla. **C–D**, *T. mundula* var. *scabrida*: **C**, detail of floral characters; **D**, detail of the stem and leaf morphology. — InBr1, inflorescence bract 1; InBr2, inflorescence bract 2; Lf, leaf. — All field photos by M.O.O. Pellegrini.

Cymbispatha. Nevertheless, the inflorescence on the right side, shown in lateral view, clearly shows that the bracts are separate from each other (Fig. 1A, InBr1 and InBr2). Moreover, the androecium details on the plate show six, equal-length stamens, with apparently rhomboid connective and punctate stigma (Fig. 1B).

Seubert (1855) described *Tradescantia mundula* var. *scabrida* (Fig. 1C–D) where he cited only Sellow “crescit in Brasilia meridionali” in the protologue. The material “F. Sellow 3852” was identified by Seubert himself as *T. mundula* var. *scabrida* and is well preserved, thus being the best option for a lectotype.

Tradescantia geniculata Vell. was cited by Clarke (1881) and Pichon (1946) as an accepted species and by Hunt (1980) as a name of uncertain status. Apart from that, it has remained neglected in recent Commelinaceae papers.

Taxonomical notes. – Vellozo’s description, in which he considers the stems as reptant, the leaves as cordate-oblong and the calyx (called by him “receptaculum”) as villous leaves no doubt regarding the inclusion of this name under the synonymy of *Tradescantia mundula* var. *scabrida*. It can be characterized by its velutine and fleshy leaves, which are bluish-green adaxially and vinous abaxially, with the secondary veins inconspicuous. The velutine hairs are hyaline and adpressed to the leaves making them hard to see with the naked eye, but are evident under the stereomicroscope.

4. *Tradescantia commelina* Vell., Fl. Flumin.: 140. 1829, nom. illeg., non Neuenh. 1797 – **Lectotype (designated here):** [illustration] Original parchment plate of *Flora fluminensis* in the Manuscript Section of the Biblioteca Nacional, Rio de Janeiro [cat. no.: mssl198652_158] and later published in Vellozo, Fl. Flumin. Icones 3: t. 154. 1831).

= *Tripogandra diuretica* (Mart.) Handl. in Rhodora 77: 259. 1975 = *Tradescantia diuretica* Mart.

Nomenclatural notes. – The illegitimate name *Tradescantia commelina* Vell. is a later homonym of *T. commelina* Neuenh. (= *Tinantia erecta* (Jacq.) Fenzl). This name was cited by Clarke (1881) and Handl. (1975) as a synonym of *Tripogandra diuretica*.

Taxonomical notes. – The plate presented for *Tradescantia commelina* (Vellozo, 1831: t. 154) clearly matches *Tripogandra diuretica* due to its linear-lanceolate leaves with an asymmetric base (those congested at the apex of the stem) and obovate petals. Also, the description cites the dimorphic stamens (characteristic of the genus), with barbate upper stamens.

■ RESULTS AND DISCUSSION

With the exclusion of *Tradescantia geniculata* Vell. from *T. sect. Cymbispatha*, the latter ceases to be represented in Brazil. The taxonomical confusion regarding *T. cymbispatha* C.B.Clarke will be dealt with in a future paper (Pellegrini & al., in prep.). The application and the sectional position of *T. repens* Vand. and *T. valida* G.Brückn. is still uncertain, with further investigations needed.

Thus, *Tradescantia* in Brazil is represented by three naturally occurring sections (*T. sect. Austrotadescantia*, *T. sect. Campelia* (L.C.Rich.) D.R.Hunt, *T. sect. Mandonia* D.R.Hunt) and a sub-spontaneous one (*T. sect. Zebrina* (Schnizl.) D.R.Hunt, which is native from Mexico). *Tradescantia* sect. *Campelia* is monospecific (Hunt 1986), and *T. sect. Mandonia* and *T. sect. Zebrina* are represented in Brazil by one species each (*T. ambigua* Mart. and *T. zebrina* Heynh. ex Bosse, respectively). *Tradescantia* sect. *Austrotadescantia* is represented by about 10 species. A key for the sections of *Tradescantia* occurring in Brazil is presented below.

Key to the Brazilian sections of *Tradescantia*

1. Leaves spirally alternate; inflorescences axillary 2
1. Leaves distichously alternate; inflorescences terminal or terminal and axillary 3
2. Inflorescences perforating the leaf-sheath, pedunculate; sepals fleshy, vinous and tightly enclosing the capsule (forming a berry-like fruit); petals obovate, white; anthers white, connective sagitate; ovary glabrous; stigma trilobate *T. sect. Campelia*
2. Inflorescences not perforating the leaf-sheath, sessile; sepals membranous, green, loosely enclosing the capsule; petals ovate to elliptic, pinkish to lilac; anthers yellow to yellowish-orange, connective rectangular to rhomboid; ovary hirsute; stigma truncate *T. sect. Mandonia*
3. Cincinnus bracts conduplicate, falciform; sepals irregularly fused; petals clawed, fused in the mid portion of the claw (flowers tubular); stamens subequal, epipetalous, connective tapered; style cylindrical with obconical apex; stigma trilobate *T. sect. Zebrina*
3. Cincinnus bracts leaf-like and slightly smaller than the leaves; sepals free; petals not clawed, free (flowers flat); stamens equal, free, connective rhomboid; style cylindrical with conical apex; stigma punctate *T. sect. Austrotadescantia*

■ ACKNOWLEDGEMENTS

The authors would like to thank the CAPES (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior) for a M.Sc. scholarship to Marco Octávio de Oliveira Pellegrini. Rafaela Campostrini Forzza and Cassia Mônica Sakuragui are CNPq research fellows. We thank Haroldo Cavalcante de Lima for providing access to bibliographic material from his personal collection, and William Antonio Ferreira and José Floriano B. Pastore for sending further bibliographic material. We also thank Luana Silva Braucks Calazans, Thiago Erir Cadete Meneguzzo, Daniela Zappi, and two anonymous reviewers for suggestions on the manuscript. This study was carried out as part of a Master’s degree in Biodiversity and Evolutionary Biology by Marco Octávio de Oliveira Pellegrini at Programa de Pós-Graduação em Biodiversidade e Biologia Evolutiva, Instituto de Biologia, Universidade Federal do Rio de Janeiro – IB/UFRJ.

13

16 **Abstract.**

17 Towards a better understanding on the taxonomy of the enigmatic *Tradescantia*
18 *cymbispatha* C.B.Clarke (Commelinaceae) – the source of the taxonomical confusion
19 between *Tradescantia* sect. *Astrotradescantia* and sect. *Cymbispatha* – we reexamined
20 the protologues of *T. geniculata* Vell., *T. mundula* var. *scabrida* Seub., *T. cymbispatha*
21 C.B.Clarke var. *cymbispatha* and *T. cymbispatha* var. *vilosissima* C.B.Clarke, *C.*
22 *geniculata* Pichon, *T. cerinthoides* Kunth, and *T. koernickeana* Seub. Our analysis
23 revealed a great deal of confusion caused by a misinterpretation of Vellozo's plate for *T.*
24 *geniculata*. We conclude that *T. cymbispatha* is the accepted name for *T. geniculata*.
25 Clarke's descriptions were based on a miscellaneous assembling of three different
26 species of *Tradescantia*, and *T. cymbispatha* var. *vilosissima* does not represent a
27 variety, but it is in fact a synonym of *T. cerinthoides*. Due to this misunderstanding, a
28 new *Tradescantia* species from Bolivia remained undescribed until now. More
29 importantly, we clear the taxonomical confusion between these two sections and
30 provide a table of morphological characters that distinguish them from each other.

31 **Keywords.**

32 *Astrotradescantia*, Brazil, *Cymbispatha*, Neotropical flora, Tradescantiinae, spiderwort

33

34 **INTRODUCTION**

35 In the last revision of Commelinaceae, Clarke (1881) published the most
 36 comprehensive taxonomic treatment of *Tradescantia* L. to date. This treatment
 37 recognized 36 species arranged in three sections. The first section, *Eutradescantia*, was
 38 characterized by having six equal to sub-equal stamens; the second, *Descantaria*, was
 39 characterized by having dimorphic stamens; and the third, *Monantha*, was characterized
 40 by one-flowered axillar inflorescences. Currently, 12 sections and approximately 80
 41 species are recognized in the genus (Faden, 1998; Hunt, 1975, 1980, 1986), with
 42 sections *Austrotradescantia* and *Cymbispatha* presenting rather complicated taxonomic
 43 histories and different unresolved names.

44 *Tradescantia cymbispatha* C.B.Clarke is the source of the long-standing
 45 confusion between section *Austrotradescantia* and section *Cymbispatha* (Pellegrini &
 46 al., 2015). It all began with Clarke's (1881) mention of *T. geniculata* Vell. (as *T.
 47 giniculata*) on his species' protologue, as a synonym of his new name (Pellegrini & al.
 48 2015). Clarke considered *Tradescantia cymbispatha* to be close to *T. commelinoides*
 49 Schult. & Schult.f. due to its six unequal stamens, fused spathaceous cincinni bracts and
 50 lateral embryotega. Clarke (1881: 296) also cites herbaria specimens from Bolivia and
 51 Brazil (from the states of Minas Gerais and São Paulo), while *T. geniculata* was
 52 described from state of Rio de Janeiro (Vellozo 1829). However, no other specimen
 53 matching Clarke's (1881) concept of this species has been found in Brazil since then,
 54 despite intensive fieldwork and an extensive survey of *Tradescantia* and its relatives in
 55 herbaria. *Tradescantia cymbispatha* was considered of doubtful application by Hunt
 56 (1980), have been used in that way in three floras (Barreto, 1997; Aona, 2010; Aona &
 57 Pellegrini, 2015) and having been neglected in two others (Barreto, 2005; Aona, 2009).

58 In their revision of the *Tradescantia* names published by Vellozo, Pellegrini & al.
 59 (2015) asserted that there is a great deal of taxonomical confusion involving *T.
 60 geniculata* and *T. cymbispatha*, and that some riddles remain unsolved. In order to better
 61 understand this enigmatic name, we reexamined the protogues of all names potentially
 62 associated to the issue. In our analysis, it became clear that *T. cymbispatha* should be
 63 the accepted name for *T. mundula* var. *scabrida* Seub., that the description provided by
 64 Clarke was based on a miscellaneous assembling of three different *Tradescantia*
 65 species, that *T. cymbispatha* var. *vilosissima* C.B.Clarke does not represent a variety,
 66 but is in fact a synonym of another species, and finally, that this confusion supports a
 67 neglected new *Tradescantia* species from Bolivia.

68 **METHODS**

69 We reexamined the protogues of *T. geniculata* Vell., *T. mundula* var. *scabrida*,
 70 *T. cymbispatha* C.B.Clarke var. *cymbispatha* and *T. cymbispatha* var. *vilosissima*, *C.
 71 geniculata* Pichon, *T. cerinthoides* Kunth, and *T. koernickeana* Seub. Additional
 72 specimens from the following herbaria were also analyzed: B, G, K, LPB, MO, NY, P,
 73 S and US (herbarium acronyms following Thiers, cont. updated).

74 The terminology of indumenta and shapes follows Radford & al. (1974);
 75 inflorescence and morphology terminology follows Weberling (1965, 1989) and Panigo
 76 & al. (2011), with some modifications; fruit terminology follows Spjut (1994); and seed
 77 terminology follows Faden (1991). The conservation status was proposed following the
 78 recommendations and criteria of *IUCN Red List Categories and Criteria, Version 3.1*
 79 (IUCN, 2001). GeoCAT (Bachman & al., 2011) was used for calculating the Extent of
 80 Occurrence (EOO) and the Area of Occurrence (AOO). The map was elaborated using
 81

82 the software QGIS 2.6.1., data referring to the altitudinal gradient was taken from
 83 Worldclim (Hijmans & al. 2005) and the distribution records were taken from the
 84 analyzed herbaria material. Table 2, which presents the differences between
 85 *Tradescantia* section *Austrotradescantia* and section *Cymbispatha*, was compiled based
 86 on our ongoing revision of *Tradescantia* section *Austrotradescantia* (Pellegrini & al., in
 87 prep.), herbaria and field material, on species protogues and other specialized
 88 literature.

89

90 THE IDENTITY AND APPLICATION OF *TRADESCANTIA CYMBISPATHA*

91 In his *Flora Fluminensis*, Vellozo (1829) described four new *Tradescantia*
 92 species, one of them being *Tradescantia geniculata*. This is the oldest name for this
 93 species, but it was rendered illegitimate since it is a posterior homonym of *T. geniculata*
 94 Jacquin [= *Gibasis geniculata* (Jacq.) Rohweder] (Art. 54.1 of the *Code*, McNeill & al.,
 95 2012; Pellegrini & al. 2015). In his taxonomic revision of Commelinaceae, Clarke
 96 (1881) introduced different new genera and species for the family, but only four new
 97 names were proposed for *Tradescantia*. *Tradescantia cymbispatha* C.B.Clarke which
 98 was indirectly, but validly, proposed as a replacement name (Art. 41.3 of the *Code*,
 99 McNeill & al., 2012) for the illegitimate *Tradescantia geniculata* Vell. (Jones & al.,
 100 1981). As noted by Pellegrini & al. (2015), *T. geniculata* Vell. is a synonym of the older
 101 *T. mundula* var. *scabrida* Seub. After intense field work in South and Southeastern
 102 Brazil it became clear that this taxon merited the species rank. Nevertheless, as names
 103 have no priority outside the rank in which they were published (Art. 11.2 of the *Code*,
 104 McNeill & al., 2012), Clarke's name is the correct name for this species. Also,
 105 according to the *Code* (Art. 7.4, McNeill & al., 2012), the type of *T. cymbispatha* is to
 106 be considered the same as Vellozo's *T. geniculata* (1831: t. 153) and not the "G.
 107 Mandon 1237" specimen from Bolivia, as previously understood by some (e.g. Tropicos
 108 2014).

109 After examining all specimens cited by Clarke (1881: 296), it became clear that
 110 they belong to three different species, namely *T. cerinthoides* Kunth, *T. umbraculifera*
 111 Hand.-Mazz., and an undescribed new species from Bolivia. This analysis enabled us to
 112 conclude that Clarke's description of the vegetative morphology of *T. cymbispatha* var.
 113 *cymbispatha* is based on the material "A. St.-Hilaire 548" (which represents *T. umbraculifera*),
 114 from the state of Minas Gerais, Brazil, whereas the description of the reproductive
 115 (inflorescence, flower, fruit and seed) morphology is solely based on the
 116 "G. Mandon 1237" specimen. His description of *T. cymbispatha* var. *vilosissima* is also
 117 a miscellaneous assembling, since the vegetative morphology is based on the "A. St.-
 118 Hilaire 1500" (which represents *T. cerinthoides*) specimen from São Paulo, Brazil,
 119 whereas the description of the reproductive morphology is solely based on the "G.
 120 Mandon 1237" specimen. Nevertheless, as Clarke cited only one specimen for *T.*
 121 *cymbispatha* var. *vilosissima*, no typification is needed.

122 Since the specimens listed by Clarke (1881) represent three different species of
 123 *Tradescantia*, his description of *T. cymbispatha* represents a miscellaneous assembling
 124 and should not be regarded as a characterization of this species. Diagnostic features for
 125 this species are given in Pellegrini & al. (2015), under the name *Tradescantia mundula*
 126 var. *scabrida*, and a complete description will be presented in the ongoing taxonomic
 127 revision of *Tradescantia* sect. *Austrotradescantia* (Pellegrini & al., in prep.).

 136 Biblioteca Nacional of Rio de Janeiro [cat. no.: mss1198652_157] and later
 137 published in Vellozo, Fl. Flumin. Icones 3: t. 153. 1831 -- Epitype (designated by
 138 Pellegrini & al. 2015): BRAZIL. Rio de Janeiro, Petrópolis, bairro Castelânea, fl.,
 139 8 Aug 2010, M.O.O. Pellegrini 17 (RB No. 595794!; isoepitype: RFA No.
 140 36865!).
 141 = *Tradescantia mundula* var. *scabrida* Seub. in Martius, Fl. Bras. 3(1): 249. 1855, **syn.**
 142 **nov.** -- Lectotype (designated by Pellegrini & al. 2015): BRAZIL. s. loc., s. dat.,
 143 F. Sellow 3852 (B barcode B 10 0247278!).
 144

- 145 **2. *Tradescantia cerinthoides* Kunth, Enum. Pl. 4: 83. 1843 -- Lectotype (designated
 146 here): BRAZIL. Brasilia meridionalis, Dec. 1836, F. Sellow 2963 (B 2ex barcode
 147 B 10 0521011!, B 10 0521012!; isolectotypes: K barcode K 000363273!).**
- 148 = *Tradescantia cymbispatha* var. *villosissima* C.B.Clarke, in De Candolle, Monogr.
 149 Phan. 3: 296. 1881, **syn. nov.** Holotype: BRAZIL. Provicia de São Paulo, s. die,
 150 A. St.-Hilaire 1500 (P barcode P 02174044!).
- 151 = *Tradescantia koernickeana* Seub. in Martius, Fl. Bras. 3(1): 249. 1855 -- **Lectotype
 152 (designated here): BRAZIL Rio Grande do Sul, Rio Pardo, 23 Sept. 1833, F.
 153 Sellow 3033a (B barcode B 10 0521013!; isolectotype: K barcode K 001040251!).**

155 **Comments.** — When describing *T. cerinthoides*, Kunth (1843) cites that the
 156 specimen in which he based his description was a collection from Sellow from southern
 157 Brazil. Seubert (1855) cites collections by Sellow as examined material for the same
 158 region and for the municipality of Rio Pardo, state of Rio Grande do Sul, as he describes
 159 *T. koernickeana*. Clarke (1881) considers *T. koernickeana* a synonym of *T. cerinthoides*
 160 and cites two materials (“*F. Sellow 2963*” and “*F. Sellow 3033a*”), which are considered
 161 as syntypes of the latter. Hunt (2001) cites “[T: Brazil, Rio Grande do Sul *F. Sellow*
 162 3033a [B, K (fragment)]]” as the lectotype for *T. cerinthoides*, indicating the material
 163 was at B and K, but as the author did not indicate that an lectotype was being
 164 designated, a valid typification was not accomplished (Art. 7.10 of the *Code*, McNeill &
 165 al., 2012). Nonetheless, “*F. Sellow 2963*” matches perfectly the descriptions provided
 166 by Kunth (1843) and Seubert (1855) for *T. cerinthoides*, but most importantly it
 167 possesses a description and an attached illustration, in Kunth’s handwriting. In face of
 168 the above mentioned, we designate “*F. Sellow 2963*” as the lectotype for *T.
 169 cerinthoides*.

170 After analyzing “*F. Sellow 3033a*” materials at B and K, we noticed that they
 171 fitted perfectly into Seubert’s concept of *T. koernickeana*, and the specimens matched
 172 the specifications given by the author on the species protologue. The specimen
 173 deposited at B was identified as *T. koernickeana* by Seubert himself. Thus, the specimen
 174 at B seems to be the logical choice for a lectotype

175

176 NAMING THE UNNAMED

177 Several misinterpretations of Vellozo's plate (e.g. Clarke 1881; Pichon 1946) led
 178 different authors to believe that the specimen from Bolivia had already been described.
 179 Until now, this species has been mistakenly treated as *T. cymbispatha* and remained
 180 officially unnamed. Therefore, it is described below as *Tradescantia praetermissa*
 181 M.Pell.

182

183 *Tradescantia praetermissa* M.Pell., sp. nov., Fig. 1

192

193 **Herbs** perennial, terrestrial or rupicolous, ca. 20–70 cm tall. **Roots** thin, fibrous. **Stem**
 194 decumbent to ascending, delicate to slightly succulent, branching at the base, rarely
 195 branching at the upper half, rooting at the basal nodes; internodes 3.8–15.9 cm long at
 196 base, distally shorter, green with vertical reddish-purple striations to reddish-purple with
 197 green spots, glabrous, with a leaf-opposed longitudinal line of short, uniseriate, light-
 198 brown to hyaline hairs in the terminal portion of the stems. **Leaves** distichously-
 199 alternate, sessile to subpetiolate; sheaths 0.7–2.6 cm long, green, hirsute turning
 200 glabrous towards the apex, margin densely ciliate, hairs light-brown to hyaline; petiole
 201 ca. 0.1–1.1 cm long to indistinct; blades elliptic to broadly elliptic to ovate to broadly
 202 ovate, 1.7–10.4 × (0.7–)1.1–3.6 cm, flat, membranous, densely hirsute on both sides
 203 turning sparsely hirsute to glabrous towards the apex of the stems, adaxially glossy
 204 light-green, abaxially slightly lighter, rarely vinous tinted, turning olive-green to light-
 205 brown when dry, base symmetrical to slightly asymmetrical, cordate to obtuse, rarely
 206 cuneate, margin green to reddish-purple, entire, slightly revolute, apex acute to
 207 acuminate; midvein conspicuous, adaxially impressed, abaxially prominent, rounded,
 208 secondary veins conspicuous, adaxially slightly impressed, abaxially inconspicuous,
 209 becoming more evident on both sides when dry. **Inflorescences** terminal or axillar in
 210 the distal portion of the stems, composed of a solitary main florescence or a main
 211 florescence with 1–2 paraclades; main florescences a pedunculate double-cincinni fused
 212 back to back; peduncles 0.6–3.3 cm long, green, glabrous with a dense longitudinal line
 213 of short, uniseriate, light-brown to hyaline hairs; supernumerary bracts sometimes
 214 present, leaf-like to slightly spathaceous, the same size as the leaves; peduncle bracts
 215 present or not, bladeless sheaths, rarely with a reduced leaf-like blade, 1–2(–3) per main
 216 florescence; cincinni bracts similar to each other, broadly cordate to cordate, 0.9–2.5 ×
 217 1–2 cm, spathaceous, spread, hirsute to sparsely hirsute only at the margins to glabrous
 218 on both sides, adaxially yellowish-green to light-green, abaxially slightly lighter, base
 219 cordate to obtuse, overlapping, rarely separate from each other, fused, margin minutely
 220 ciliolate becoming setose towards the base of the bract, apex acute; double cincinni ca.
 221 (2–)4–8-flowered, condensed; bracteoles expanded, linear, hyaline. **Flowers** bisexual,
 222 weakly zygomorphic due to calyx zygomorphy, ca. 1.5–2 cm diam., pedicels 3–5.8 mm
 223 long, green, glabrous, geniculate at pre-anthesis and anthesis, reflexed at post-anthesis;

224 floral buds ovoid, zygomorphic, apex acute; sepals unequal, ovate, cucullate, 3.4–6.4 ×
 225 2–3 mm, green, margin hyaline, apex acute, the uppermost bigger than the inferior two,
 226 keeled, with long hyaline hairs along the keel, the lower two not-keeled, glabrous; petals
 227 rhomboid to obovoid, not-clawed, 0.7–0.8 × 0.7–1 cm, white, base cuneate, margin
 228 entire, apex obtuse to slightly rounded; stamens 6, in two whorls, unequal in length, the
 229 outer whorl opposite to the sepals, shorter, the inner whorl opposite to the petals, longer,
 230 filaments 3–7 mm long, distally sparsely bearded, hairs white, moniliform, much shorter
 231 than the filaments, anthers ca. 1–1.5 × 0.8–1.1 mm, connective expanded, subcordate to
 232 rhomboid-cordate, yellow, anther sacs globose to slightly elliptic, light-yellow, pollen
 233 white colored; ovary sub-globose, 1.1–1.2 × 0.5–0.7 cm, white, glabrous, locules 3,
 234 equal, 2-ovulate, style 1.8–2 cm long (shorter than the stamens), straight, white, stigma
 235 subtrilobate, white. **Capsule** ellipsoid, apiculate due to persistent style base, 3.5–5.5 ×
 236 2–2.7 cm, brown when mature. **Seeds** uniseriate, 1–2 per locule, ellipsoid to narrowly
 237 trigonal, ventrally flattened, 1.9–2.3 × 1–1.4 mm, brownish to greyish-brown, testa
 238 rugose arranged in radiated ridges, hilum linear, ½ the length of the seed, embryotega
 239 semi-lateral.

287 **Etymology.** — The epithet means “overlooked”, “ignored”, in reference to this
 288 species being neglected for such a long time.

289 **Distribution.** — It is known to occur in Bolivia, Ecuador and Peru (Fig. 2).

290 **Habitat.** — It is known to occur in the Andean region, rocky outcrops, wooded
 291 slopes, moist cloud forest and moist forested valleys, between 1600--3200 m above the
 292 sea level.

293 **Phenology.** — Blooming from November throughout June and fruiting from
 294 March to June, more rarely in December.

295 **Conservation status.** — The degradation of the Larecaja region, Bolivia, by
 296 farming, has caused the disappearance on many native species (Ochoa, 2001) which
 297 reflects in the few recent collections of this species for this region. Nevertheless, *T.*
 298 *praetermissa* seems to be a common plant elsewhere, growing at road sides and forest
 299 trails throughout its EOO (around 669,800.000 km²) and its AOO (around 52,000.000
 300 km²). Thus, we consider this species Least Concern (LC) according to the IUCN
 301 criteria.

302 **Affinities.** — *Tradescantia praetermissa* was first compared by Clarke (1881, as
 303 *T. cymbispatha*) with *T. commelinoides*, the only other species from *Tradescantia*
 304 section *Cymbispatha* described at the time. They are similar due to the spread cinnini
 305 bracts, rhomboid to broadly obovate petals, glabrous ovaries and the rugose-alveolate
 306 testa, but differ from each other due to root morphology, the presence of supernumerary
 307 bracts, petal color, filament bearding, connective shape and color. *Tradescantia poelliae*
 308 D.R.Hunt, was segregated from the *T. commelinoides* complex (Hunt 1981), due to root
 309 morphology, filaments bearding, connective color and shape and seed ornamentation,
 310 among others differences. The same characters that differentiate *T. poelliae* from *T.*
 311 *commelinoides*, bring it closer to *T. praetermissa*, but they can be differentiated by
 312 many other morphological characters. Nevertheless, *T. praetermissa* is more closely
 313 related to *T. gracillima* Standley, due to the presence of supernumerary bracts, petal
 314 color, glabrous ovaries and ornamentation of the testa. They can be differentiated from
 315 each other by their cinnini bracts, petal shape, filaments bearding, connective shape
 316 and seed color (Table 1). The specimens from Panama identified as *T. cymbispatha*
 317 represent *T. gracillima*.

318

319 **ON THE BOUNDARIES BETWEEN *TRADESCANTIA* SECTION
320 *AUSTROTRADESCANTIA* AND SECTION *CYMBISPATHA***

321 In order to deconstruct the myth of a diffuse morphological boundary between
322 *Tradescantia* section *Austrotradescantia* and section *Cymbispatha*, we provide a list of
323 morphological characters that differentiate them from each other (Table 2). We reaffirm
324 that no representatives of *Tradescantia* section *Cymbispatha* are known to occur in the
325 Brazilian territory, as previously stated by Pellegrini & al. (2015). *Tradescantia* sect.
326 *Cymbispatha* ranges from Mexico to Bolivia (Andean region), with no overlap with the
327 distribution of *Tradescantia* sect. *Austrotradescantia*, which naturally ranges from
328 Southeastern and Southern Brazil (its diversity center) to Argentina, Paraguay, Uruguay
329 and Bolivia (Chaco region).

330
331 **CONCLUSION**

332 Systematic monographs are the only known mechanism for achieving quality
333 control in taxonomy and reducing the number of synonyms that clutter up databases and
334 hinder progress in our knowledge of the world's biodiversity and its conservation status
335 (Carvalho & al., 2014). Nevertheless, monographs that embrace all species in a given
336 group are only as good as the local research and collections that form their foundation.
337 The most typical path chosen by monographers is to start understanding a defined area
338 or small group of species, increasing the range by studying other floras, examining
339 herbarium specimens, studying other aspects of the group's biology and determining the
340 group's phylogeny (Thomas & al., 2012). Although several aspects of *Tradescantia*
341 such as chemotaxonomy (Martínez & Martínez, 1993), cytology (Jones & Jopling,
342 1972) and pollen morphology (Poole & Hunt, 1980) are well known, data on its
343 systematics are still scant. The present paper represents one of the steps towards the
344 monograph of the genus, a journey which was initiated by the studies of D.R. Hunt
345 (1975, 1980, 1986) from Royal Botanic Gardens, Kew.

346
347
348 **ACKNOWLEDGEMENTS**

349 The authors would like to thank CAPES and CNPq for the award of fellowships.
350 We thank the curators and staff at B, K, MO, NY, P and US for the specimens loaned to
351 RB, the curators and staff at LPB, P and S for sending high-quality images, and Alain
352 Chautems and Catia Canteiro for sending high-quality images from G and K,
353 respectively. Luana Silva Braucks Calazans, Fernanda Santos-Silva, Rafael Felipe de
354 Almeida and Mauro de Castro Pellegrini for suggestions on an early version of the
355 manuscript. We also thank David R. Hunt and Robert B. Faden for providing relevant
356 literature, Hibert Huaylla and Alfredo Fernando Fuentes for sending field photos of the
357 new species, and Rafael Gomes Barbosa-Silva for the confection of the map. This study
358 was carried out as part of a Master's degree in Biodiversity and Evolutionary Biology
359 by Marco Octávio de Oliveira Pellegrini at Programa de Pós-Graduação em
360 Biodiversidade e Biologia Evolutiva, Instituto de Biologia, Universidade Federal do Rio
361 de Janeiro — IB/UFRJ.

Short running title: Phylogeny and taxonomic revision of *Tradescantia* sect.
Austrotradescantia

Abstract: Throughout the years, three infrageneric classifications were proposed for *Tradescantia* along with several informal groups and species complexes. The current infrageneric classification assimilates many concepts adopted by previous authors. *Tradescantia* sect. *Austrotradescantia* was described, based on the “*T. fluminensis* Vell. complex”, as the only exclusively South American section of the genus. Nevertheless, no taxonomic treatment or phylogenetic study focusing on the group was ever made. Thus, the goal of this study was to infer the phylogenetic relationship between the remaining species of *T. sect. Austrotradescantia*, using morphological characters, in order to test the monophyly of sections *Austrotradescantia* and *Cymbispatha*. This study also presents the first taxonomic revision for *Tradescantia* sect. *Austrotradescantia*, with the description of two new species and nomenclatural novelties.

Keywords: Inflorescence morphology, invasive species, Tradescantiinae, spiderworts, wandering Jew.

INTRODUCTION

Tradescantia L., as currently circumscribed, is the second largest genus (ca. 80 species) of Commelinaceae (Faden 1998; eMonocot 2010; The Plant List 2013). The family is economically important due to the ornamental value of many genera and by the great number of invasive species, especially in the genera *Commelina* L. and *Tradescantia* (Hunt 2001; Burns 2008). The genus is characterized by its main florescences composed by a double cincinni fused back to back, with each cincinni subtended by an expanded bract, actinomorphic flowers with six stamens, and seeds with linear hilum (Faden 1998; Panigo *et al.* 2011). Throughout the years, three infrageneric classifications were proposed for *Tradescantia*: Clarke (1881), Brückner (1930) and Hunt (1975, 1980, 1986). Aside from that, several informal groups and species complexes have often been recognized by different authors: e.g. Woodson (1942) and Anderson & Woodson (1935). The current infrageneric classification (Hunt 1975, 1980, 1986) assimilates many concepts adopted by previous authors. This classification also restructures the once pulverized *Tradescantia*, by reducing many segregated genera to sectional level (e.g. *Campelia* L.C.Rich., *Cymbispatha* Pichon, *Rhoeo* Hance, *Setcreasea* K.Schum. & Sydow and *Zebrina* Schniz.).

Tradescantia sect. *Austrotradescantia* was described by Hunt (1980), based on the “*T. fluminensis* Vell. complex” (Woodson 1942); as the only exclusively South American section of the genus, with its diversity center in Southeastern Brazil. It was characterized by its creeping habit, leaf-like to spathaceous cincinni bracts, free petals and stamens, dorsal embryotega and numerous and bimodal chromosomes (Jones & Jopling 1972; Hunt 1980). At the time, Hunt (1980) included five species in the section, later (2001) reducing *T. blossfeldiana* Mildbr. to a synonym of *T. cerinthoides* Kunth. Pellegrini *et al.* (2015– Capítulo 1) reestablished *T. mundula* Kunth while dealing with the *Tradescantia* names of Flora

fluminensis. While Pellegrini *et al.* (Capítulo 2) solved the application of *T. cymbispatha* C.B.Clarke and considered it a member of the group, leaving the section with six species. Other studies showed that the section also presented a rather peculiar phytochemical profile (Martínez & Martínez 1993) and stigmatic morphology (Owen 1981), which differentiated it from the remaining species of the genus. Members of this section are economically important due to the ornamental value of their leaves, being hardy-plants, and their mat-forming habit. For these same reasons, *T. fluminensis* has escaped from cultivation and has become a major weed in countries such as Australia, New Zealand, Portugal, South Africa and USA (Hunt 2001; Burns 2008; Fowler *et al.* 2013).

Tradescantia sect. *Austrotradescantia* has been recovered as monophyletic with high statistical support in the two molecular based phylogenies for *Tradescantia* (BS=84/PP=100, Burns *et al.* 2011; BS=100, Hertweck & Pires 2014). Nevertheless, only two species, *T. fluminensis* and *T. blossfeldiana* (= *T. cerinthoides*) were sampled in both studies. Thus, the phylogenetic relationship among the remaining species of the section is still unknown. As pointed out by Pellegrini *et al.* (2015; Capítulo 2), there seems to be a confusion on the morphological limits between sections *Austrotradescantia* and *Cymbispatha*. Some species have been sometimes positioned in one section or in the other due to this misinterpretation.

Despite possessing few species, *Tradescantia* sect. *Austrotradescantia* has a complicated taxonomic history (Capítulo 2), due to many continuous and reticulate morphological characters (Martínez 1984), which makes terminology adopted by Woodson (1942) of “species complex” rather appropriate for this group (Pellegrini *et al.* 2013). Despite that, no taxonomic revision has ever been made for the section and no identification key is available for the group. Thus, the goal of this study was to infer the phylogenetic relationship between the remaining species of *Tradescantia* sect. *Austrotradescantia*, using

morphological, cytological and phytochemical characters; in order to test the monophyly of sections *Austrotradescantia* and *Cymbispatha*, and the boundaries between them. This study also presents the first taxonomic revision for *Tradescantia* sect. *Austrotradescantia*, including an identification key, synonyms, descriptions, comments, illustrations, distribution maps and conservation status, for all species.

METHODS

PHYLOGENETIC ANALYSIS

Taxon Sampling: Our study includes sampling from 49 taxa of the *Tradescantia* alliance, including all four genera currently accepted for subtribe Tradescantiinae (i.e. *Callisia*, *Gibasis*, *Tradescantia* and *Tripogandra*) and two genera from subtribe Thysanthesminae (i.e. *Elasis* D.R.Hunt and *Tinantia* Scheidw.). Our ingroup includes all the 10 species of *Tradescantia* sect. *Austrotradescantia* accepted in the present study, six species from section *Cymbispatha*, four species from section *Tradescantia* (i.e. representatives from all four series: *Orchidophyllae*, *Sillamontanae*, *Virginianae* and *Tuberossae*), two species from section *Setcreasea* and a single species of sections *Campelia*, *Coholomia*, *Corinna*, *Mandonia*, *Parasetcreasea*, *Rhoeo*, *Separotheca*, and *Zebrina*, totaling 30 *Tradescantia* (ca. 38% of the genus). Type species from all section and series currently accepted for *Tradescantia* were sampled. Outgroup is represented by five *Gibasis* (with representatives from both sections *Gibasis* and *Heterobasis*), six *Callisia* (with representatives from sections *Hadrodemas*, *Leptocallisia* and *Callisia*), five *Tripogandra* and the monotypic *Elasis*, and rooted in two *Tinantia*. Details of voucher specimens are given in Table 1.

Character Selection and Coding: Characters were scored mainly from living specimens at the field and specimens kept at the Jardim Botânico do Rio de Janeiro greenhouses, and later complemented by spirit and herbarium samples from the same herbaria visited for the taxonomic revision. When living or herborized specimens were not available for examination, information was taken from published literature (Table 2). Character coding followed the recommendations of Sereno (2007) for morphological phylogenies. Primary homology hypotheses (De Pinna 1991) were proposed for root, stem, leaf, inflorescence architecture, floral, fruit, seed, palynological, anatomical characters, phytochemical and cytological characters (which are partly illustrated in Fig. 1). A total of 86 characters were scored, with 76 macromorphological, one palynological, two anatomical, three cytological and four phytochemical.

Phylogenetic Analysis: Data was entered into a matrix of characters per taxa using the software Mesquite 2.73 (Madison & Madison 2010). All characters were treated as unordered. Maximum parsimony (MP) analysis was performed using PAUP* 4. (Swofford 2003), with a heuristic search with 1000 random taxon additions and tree bisection–reconnection (TBR) branch swapping. The consistency (CI) and retention indexes (RI) were calculated. We used the character optimization criterion of ACCTRAN (accelerated transformation optimization) (Swofford & Maddison 1987). Statistical support for each branch of the cladogram was evaluated via bootstrap (BS) analyses with 1000 random addition replication. The search parameters used to estimate the bootstrap values were the same as the initial heuristic search. We also evaluated clade reliability by using the Bremer index (BI) (Bremer 1994) and the presence of secondary homologies. The characters were optimized on the majority-rule (50% values) consensus trees using Mesquite 2.73 and WinClada ver. 1.0000 (Nixon 2002).

TAXONOMIC REVISION

For a better understanding on the morphological variation of species, we gathered ecological data, live samples for cultivation, new spirit and herbaria vouchers, and field trips. Field trips were performed from 2010 to 2015 throughout the distribution range of the group in Southeastern and Southern Brazil. Live specimens were cultivated in Jardim Botânico do Rio de Janeiro's greenhouse, in order to observe, photograph and analyze fresh flowers, fruits and seeds as well as other phenological data. The description of species, phenology and illustrations were based on herborized, spirit, fresh, and cultivated specimens, besides observations. Fertile collections were deposited in RB herbarium. Additional specimens from the following herbaria were also analyzed: B*, BHCB, BHZB*, CESJ, CORD*, CTES*, ESA, FLOR, FURB, GUA, HAS, HB, HBR, HUSC*, IAC, ICN*, INPA*, K, LIL*, LPB*, M*, MBM, MBML, MO*, NY*, P*, R, RB, RFA, RFFP, S*, SI*, SP, SPF, UEC, UPCB, US*, VIC* & WU* (herbaria acronyms according to Thiers, continuously updated). Herbaria acronyms with * were had their collections borrowed to RB.

The terminology of indumenta and shapes follows Radford *et al.* (1974); inflorescence morphology terminology follows Weberling (1965, 1989) and Panigo *et al.* (2011), with some modifications; fruit terminology follows Spjut (1994); and seed terminology follows Faden (1991). The conservation status was proposed following the recommendations and criteria of *IUCN Red List Categories and Criteria, Version 3.1* (IUCN, 2001). GeoCAT (Bachman *et al.*, 2011) was used for calculating the Extent of Occurrence (EOO) and the Area of Occurrence (AOO). The maps were elaborated using the software QGIS 2.6.1., data referring to the altitudinal gradient was taken from Worldclim (Hijmans *et al.*, 2005) and the distribution records were taken from the analyzed specimens.

RESULTS

The cladistic analysis retrieved 5,000 equally parsimonious trees with 424 steps, Consistency Index (CI) of 0.3066 and Retention Index (RI) of 0.7042. From 86 studied characters, 82 were parsimony-informative. The monophyly of *Tradescantia* in its present circumscription is not supported by our analysis due to the position of *T. guatemalensis* (sect. *Coholomia*) as sister to *Elasis hirsuta* (BS= 99; BI= 3) (Fig. 2, 3). This relation can be also observed in the strict consensus (Fig. 5). With the exclusion of *T. guatemalensis*, the synapomorphies supporting the *Tradescantia* s.s. clade (BI= 1) are: erect stems (Character 2), expanded cinni bracts (Character 34), the ellipsoid to rectangular seed (Character 74, which is a reversion) and leaf epidermis without silica crystals in specialized cells (Character 78, which is a reversion) (Fig. 4). Character 34 suffers only one reversion, being the synapomorphy supporting *T. ambigua* + *T. andrieuxii*. In the strict consensus tree *T. guatemalensis* is also recovered sister to *Elasis* (Fig. 5). This relation is supported by the following synapomorphies: leaves hirsute abaxially (Character 13), pilose sepals (Character 49, homoplastic), filaments sparsely medially bearded with long moniliform hairs (Characters 57–60), pistil shorter than the stamens (Character 71, homoplastic) (Fig. 4). It can be differentiated from *Tradescantia* s.s. by the following characters: reduced cinni bracts (Character 34), 1–several pedunculate free cinni (Characters 26, 28, 31), anther connectives not expanded (Characters 65–66), silica crystals in specialized cells with thickened walls (Character 78, homoplastic), mesophyll with bundle sheath sclerenchymatic extensions (Character 79, homoplastic) and chromosome number $n= 4–5$ (Character 80). *Gibasis* is recovered as polyphyletic, split in three different clades (Fig. 4). *Tripogandra* was recovered monophyletic (BS= 67; BI= 1). *Callisia* is also recovered as polyphyletic, due to the position of *C. filiformis* as sister to *Tripogandra*, and *C. warszewicziana* as sister to

(*Tripogandra* + *C. filliformis*) + *Callisia* s.s. (BS= 56; BI= 1). The clade composed by *Tripogandra* + *Callisia* (BI= 1) is recovered as sister to *Tradescantia* s.s. (BI= 2) (Fig. 4).

Tradescantia sect. *Austrotradescantia* is the first clade to diverge in the genus (BS= 76; BI= 2), followed by the *Cymbispatha* clade (BS= 53; BI= 3), then by Core *Tradescantia* (Fig. 6). *Tradescantia* sect. *Austrotradescantia* is defined by the following synapomorphies: asymmetric leaf-bases (Character 16, homoplastic), keeled sepals (Character 47, homoplastic), filaments basally densely bearded with moniliform hairs (Characters 57–60, homoplastic), punctiform stigma (Characters 73), costate testa (Character 76, homoplastic), chromosomes $n= 10$ –numerous (Character 80), and bimodal chromosomes (Character 82, homoplastic) (Fig. 4). *Tradescantia* sect. *Austrotradescantia* is divided in two clades (Fig. 4). In the strict consensus *T.* sect. *Austrotradescantia* is also recovered, but with all species inside a big polytomy (Fig. 5). The first clade is named as the *Tradescantia fluminensis* group (*T. chrysophylla* M.Pell sp. nov., *T. cymbispatha*, *T. fluminensis*, *T. mundula*, *T. tenella* Kunth, and *T. umbraculifera* Hand.-Mazz.). It is sustained by the following synapomorphies: delicate and creeping stems (Characters 2–3, homoplastic), subpetiolate and flat leaves (Character 6 & 8, homoplastic), cinni bracts saccate at base (Character 37, homoplastic), and exclusively white petals (Character 55, homoplastic). Despite the low statistical support, the phylogenetic relationships of all species were well resolved, with the *T. chrysophylla* + *T. cymbispatha* clade being medially supported (BS= 71; BI= 1). The second clade is named as the *Tradescantia crassula* group (*T. cerinthoides* Kunth, *T. crassula*, *T. seubertiana* M.Pell sp. nov., and *T. valida* G.Brückn.) (BS= 52). It is sustained by the following synapomorphies: succulent and erect stems (Characters 2–3, homoplastic), sessile and complicate to falcate leaves (Character 6 & 8, homoplastic), cinni bracts not saccate at base (Character 37, homoplastic), petals varying from white to pink to lilac (Character 55, homoplastic), costate

testa (Character 76, homoplastic), and by the presence of sulfated phenolic acids (Character 86, homoplastic) (Fig. 4).

The *Cymbispatha* clade is composed by *Tradescantia* sect. *Rhoeo* sister to two clades (BS= 53; BI= 3). In the strict consensus only the clade corresponding to *T.* sect. *Cymbispatha* is still recovered, with the other clade being recovered inside a polytomy (Fig. 5). This clade is supported by the following synapomorphies: inflorescences composed of one main florescence plus 1–several paraclades (Character 22), accessory bracts present (Character 25), supernumerary bracts present (Character 33, homoplastic), spathaceous bracts (Character 35), flowers geniculate at anthesis and/or pre-anthesis (Character 43), subequal stamens (Character 61, homoplastic), connective cordate to sagitate to transversally linear (Character 65–66, homoplastic), white colored pollen (Character 69, homoplastic), lateral to semi-lateral embryotega (Character 75, homoplastic), and chromosome number varying from $n= 5$ – 6 – 7 – 8 – 10 – 11 due to Robertsonian changes (Character 80) (Fig. 4). The first clade is composed by *T.* sect. *Cymbispatha* (BI= 3), being characterized by the following synapomorphies: flat flowers (Character 40, homoplastic) and free stamens (Character 63). The second clade is composed by *T.* sections *Campelia*, *Corinna* and *Zebrina* (BS= 53; BI= 2), and is characterized by its tubular flowers (Character 40, homoplastic), fused sepals (Character 44), and epipetalous stamens (Character 63, homoplastic). Core *Tradescantia* is retrieved as a polytomy of three clades. The following synapomorphies sustain Core *Tradescantia*: tuberous roots (Character 1, homoplastic), lanceolate sepals (Character 46, homoplastic), curved to C-shaped anther sacs (Character 67–68), and the presence of hidroxiluteolin (Character 83) (Fig. 4). The first clade is composed by *T.* sections *Separotheca*, *Setcreasea* and *Tradescantia* (series *Sillamontanae* and *Orchidophyllae*), and is sustained exclusively by floral synapomorphies: obtuse leaf apex (Character 17), tubular flowers (Character 40), filaments glabrous or medially bearded with short and sparse hairs (Characters 57–60), epipetaly

(Character 63), pistil shorter than the stamens (Character 71, homoplastic) and median sized chromosomes (Character 81, homoplastic). The second clade is composed by *T.* sections *Mandonia* and *Parasetcreasea* (BS= 58), and is defined by the following synapomorphies: predominantly axillar inflorescences to spike-like sinforescences (Character 21), sessile inflorescences (Character 44), reduced cinni bracts (Character 34) and truncate stigma (Character 73). The third clade is composed by *T.* sect. *Tradescantia* (series *Virginianae* and *Tuberossae*) (BS= 83; BI= 1), having as synapomorphies the linear leaves (Character 7), truncate leaf base (Character 15, homoplastic), conspicuous secondary veins (Character 18) and filaments densely medially bearded with moniliform hairs (Characters 57–59). *Tradescantia* sect. *Tradescantia* was recovered as polyphyletic, since series *Virginianae* and *Tuberossae* form clade two and series *Sillamontanae* and *Orchidophyllae* are part of clade three, called by us the *Setcreasea* clade. *Tradescantia* sect. *Setcreasea* is also recovered as paraphyletic due to section *Separotheca* being recovered within it (BS= 66; BI= 2), being supported by its fused petal (Character 51) and by its clawed petals (Character 53) (Fig. 4). This clade is also recovered in the strict consensus (Fig. 5).

DISCUSSION

This study features the most extensive sampling of *Tradescantia* sections *Austrotradescantia* and *Cymbispatha*, and is the first morphologically based phylogenetic hypothesis for the genus. A high proportion of homoplasies were found in our analysis, being evaluated through the IC and IR indexes, the large number of homoplastic synapomorphies supporting the clades, and the median to low bootstrap values obtained for most clades. This was the expected scenario for the family (Evans & Faden 1998; Evans *et al.* 2000), where most coded characters were recovered as homoplastic and recovered poorly-resolved topologies, highly incongruent to the ones recovered by the molecular dataset (Evans *et al.*

2000). Nevertheless, the 50% majority-rule consensus recovered a hypothesis highly congruent to the two molecular based phylogenies available for *Tradescantia* (Burns *et al.* 2011; Hertweck & Pires 2014). According to Hillis (1996) simulations, the greater sampling for a certain group, the higher the support and phylogenetic resolution for it. Thus, we believe that since our analysis focused on *T.* sections *Austrotradescantia* and *Cymbispatha*, and we sampled few species of the remaining sections, much of the phylogenetic information may have been lost. Thus, we believe that future studies are needed in order to clarify these groups' evolutionary histories.

***Tradescantia* s.s. and sectional classification:** Our topology did not recover *Gibasis*, or part of it within *Tradescantia*, as previous phylogenies did (Burns *et al.* 2011; Hertweck & Pires 2014). The two genera are morphologically, anatomically, cytologically and phytochemically very distinct from each other, and our topology supports that *Tradescantia* and *Gibasis* remain as separate genera. This makes us believe that the *Gibasis* samples (i.e. *G. geniculata*, *G. linearis* and *G. oaxacana*, Burns *et al.* 2011; Hertweck & Pires 2014) that cause both genera to be recovered as paraphyletic may be misidentified or may have suffered from contamination. We were only unable to sample *G. linearis* in our analysis, but none of the sampled species grouped with *Tradescantia*.

Our results agree with the two previous studies (Burns *et al.* 2011; Hertweck & Pires 2014) and does not supported Hunt's sectional classification (1975, 1980, 1986). We recover the same three clade pattern for *Tradescantia*, what makes evident that ecology and biogeography may play a great part in the evolutionary history of the genus. The first clade is restricted to South America, while the second one is restricted to understory environments from Mexico to Argentina. The last clade is restricted to Seasonally Tropical Dry Forests (STDF), deserts and savanna formations concentrated in North America [with exception of *T.*

ambigua and *T. boliviiana* (Hassk.) J.R.Grant, which occur in the South American Dry Diagonal]. All three clades are supported by macromorphological characters, especially floral characters, cytology and phytochemistry. Nevertheless, further studies and sampling are needed in order to clarify the phylogenetic relationships inside Core *Tradescantia*.

***Tradescantia* sect. *Austrotradescantia*:** As mentioned above, many of the sections proposed by Hunt (1975, 1980, 1986) are not supported by our analysis. Nevertheless, *Tradescantia* sect. *Austrotradescantia* is invariably recovered as monophyletic regardless of the number of species sampled for the group (data not shown). The clade is also consistently recovered as sister to the remaining *Tradescantia* s.s. Both data corroborate the previously published phylogenies (Burns *et al.* 2011; Hertweck & Pires 2014) and also the phylogenetic hypothesis proposed for the genus by Martínez & Martínez (1993), based exclusively on phytochemical characters. This scenario suggests a South American origin in Tropical Rainforests for *Tradescantia*, with a subsequent occupation of the Andes and the West Indies by the *Cymbispatha* clade and a latter occupation of STDF and savannic formations by Core *Tradescantia*.

Two morphological groups can be clearly seen in *T. sect. Austrotradescantia*, being also recovered in our phylogeny (Fig. 3). The *Tradescantia fluminensis* group is composed by more herbaceous plants, with stems creeping to ascending at the apex, cincinni bracts saccate at base and petals always white. A marking exception is *T. tenella*, which possess fruticose, erect and extremely succulent stems, not saccate cincinni bracts and flowers that vary from pink to white. Nevertheless, it possesses the long subpetiolate, membranous to chartaceous leaves and conspicuous mid and secondary veins, which are characters common to this group. (Fig. 4). Since the leaves vary from membranous to chartaceous to slightly fleshy, vein pattern is very useful for species differentiation inside this clade. Both *T. fluminensis* (Fig. 11B) and

T. mundula (Fig. 12D) possess leaves with adaxially impressed secondary veins, while *T. cymbispatha* (Fig. 10D) possess inconspicuously impressed secondary veins. Cincinni bracts are useful for differentiating *T. umabraculifera*, which is the only species in the section with spathaceous bracts rather than leaf-like (Fig. 15E). The species in this group occur almost exclusively in Tropical and Subtropical Rainforests, but are also commonly found growing as weedy plants throughout their distribution. The species from the *T. fluminensis* group are of easier distinction, since there is a wide morphological variation in leaf, indumenta and inflorescence characters.

Tradescantia crassula group is composed by more succulent plants, which generally grow in open areas, with erect stems, cincinni bracts not saccate at base and petals varying from white to pink to lilac. The leaves from these species are sessile and extremely succulent, with only the midvein conspicuous, but in some individuals of *T. crassula* (Fig. 8A) and *T. seubertiana* (Fig. 13B), the leaves are so fleshy that even the midvein is adaxially inconspicuous. The petal color variation can be found in the same population, under the same ecological conditions, and is probably genetically controlled. The species from the second group are intimately related to the two southern biomes that are characterized by open and /or drier vegetation formations: the Chaco (which is part of the Dry Diagonal) and the Pampa. The species from the *T. crassula* group are morphologically very similar due to many overlapping characters and indumenta type and pattern is the most useful character for separating these species. For the same reason, all species were recovered within a polytomy. Added to this, *T. cerinthoides* and *T. crassula* (the two low land species) possess a rather wide distribution range which overlaps with the narrowly distributed *T. seubertiana* and *T. valida* (both of them restricted to high elevation sites). It is probable that despite the geographical isolation of the last two species, they have not accumulated sufficient morphological autapomorphies to help distinguishing these biological entities. Much variation is recorded for

the two widely distributed species, which leaves few taxonomically informative characters to distinguish taxa. This is the main cause of misidentifications for this group. Thus, we suggest *T. crassula* group to be targeted for phylogeographic and reproductive studies to improve and deepen understanding of the taxonomic boundaries between these taxa.

***Tradescantia* sect. *Cymbispatha* and the *Cymbispatha* clade:** Our analysis reveals that important morphological characters considered being exclusive to *Tradescantia* sect. *Cymbispatha* are actually shared with the *Cymbispatha* clade. These characters are: subequal stamens and lateral to semi-lateral embryotega. Characters like, zygomorphic sepals and pedicels the same size as the flower buds or sessile to subsessile are not exclusive to *T. sect. Cymbispatha*, but are actually homoplastic synapomorphies to the two clades (flat flower + tubular flower groups) of the *Cymbispatha* clade. Spathaceous bracts, supernumerary bracts and pollen grains white or the same color as the petals, are recovered in our analysis as homoplastic synapomorphies to the *Cymbispatha* clade. Our topology makes evident the large amount of reproductive characters (inflorescence and floral) that support the *Cymbispatha* clade. Therefore, we suggest this groups' reproductive biology to be targeted for specific studies, in order to better understand the evolution of reproductive strategies in the genus.

TAXONOMIC TREATMENT

1. *TRADESCANTIA* SECT. *AUSTROTRADESCANTIA* D.R.HUNT, KEW BULL. 35(2): 440. 1980. *Type species: TRADESCANTIA FLUMINENSIS* VELL.

= *Tropitria* Raf., Fl. Tell. 3: 68. 1837. *Type species: Tropitria crassula* (Link & Otto) Raf. (≡ *Tradescantia crassula* Link & Otto)

Herbs chamaephytes, perennial, frequently succulent, terrestrial, rupicolous or epiphytes. **Roots** fibrous, non-tuberous. **Stems** creeping to ascending at the apex to erect to fruticose, little to densely branched, rooting at the basal nodes or at the distal ones when they

touch the substrate. **Leaves** sessile to subpetiolate; distichously or spirally-alternate, evenly distributed along the stem; sheaths closed; blades entire, flat to slightly falcate and/or complicate, base asymmetrical, midvein conspicuous, adaxially impressed, abaxially prominent, rounded, secondary veins conspicuous or inconspicuous. **Inflorescences** terminal or axillar in the distal portion of stems, composed of a solitary main florescence; main florescences a pedunculate double-cincinni fused back to back; supernumerary bracts absent; peduncle bracts absent; cincinni bracts leaf-like, rarely spathaceous, differing from the leaves mostly only in size, similar to each other to widely different in size, amplexicaulous or saccate, free from each other; double-cincinni, sessile, congested, bracteoles inconspicuous, hyaline. **Flowers** bisexual, actinomorphic, chasmogamous, flat (not forming a floral tube); pedicel upright at anthesis and pre-anthesis, reflexed at post-anthesis; floral buds ellipsoid to ovoid to broadly ovoid, apex acute; sepal equal, free, ovate, cucullate, dorsally keeled, rarely without keels, margin hyaline, apex acute, persistent in fruit; petals sessile, equal, free, elliptic to ovate to broadly ovate, flat or plicate, base cuneate to obtuse, margin entire, apex acute; stamens 6, arranged in two series, equal, filaments free from the petals, basally densely bearded with moniliform hairs, hairs as long as the stamens, white, anthers basifixd, rimose, connective expanded, rhomboid, yellow, anther sacs ellipsoid, divergent, yellow, pollen yellow; ovary sessile, sub-globose, white, glabrous, 3-locular, locules equal, locule 2-ovulate, ovule uniseriate, style straight, white, cylindrical, conical at the apex, stigma punctate, pistil longer than or the same length as the stamens. **Capsule** globose, light-brown to brown when mature, loculicidal, 3-valved, sometimes apiculate due to persistent style base. **Seeds** exarillate, 1–2 per locule, ellipsoid to narrowly trigonal, ventrally flattened, testa costate to rugose arranged in radiated ridges, hilum linear, embryotega dorsal.

Distribution and habitat: *Tradescantia* sect. *Austrotradescantia* is distributed from Southern Bolivia, Paraguay, Argentina, Southeastern to Southern Brazil and Uruguay (Map

1). Its species can be found growing in understory in moist and shady forests, open fields, rocky outcrops and are especially common in disturbed areas.

Etymology: The name means *Tradescantia* from the South, making reference to the exclusively South American distribution of the section.

KEY TO THE SPECIES OF TRADESCANTIA SECT. AUSTROTRADESCANTIA

1. Leaf-blades linear-lanceolate to lanceolate, base truncate to amplexicaulous to obtuse, apex acuminate; 1–3 inflorescences per leaf axis, cincinni bracts spathaceous, rarely leaf-like..... *T. umbraculifera*

1. Leaf-blades elliptic to ovate to obovate, base cuneate to obtuse to cordate, apex acute, rarely acuminate; always 1 inflorescence per leaf axis, cincinni bracts always leaf-like..... 2

2. Stem erect to ascending; all leaves sessile, blades falcate to complicate; cincinni bracts not saccate at base; pistil longer than the stamens..... 3

3. Leaves distichously-alternate to spirally-alternate, blades with indumenta on both sides or only abaxially, rarely glabrous on both sides, secondary veins adaxially slightly impressed; pedicels and sepals velutine to glandulous to sparsely hirsute to hirsute, sepals without keels..... *T. cerinthoides*

3. Leaves always distichously-alternate, blades glabrous on both sides, secondary veins adaxially inconspicuous; pedicels glabrous, sepals glabrous or with few hairs at the apex or restricted to the keel, sepalskeeled..... 4

4. Leaf-sheaths margins glabrous; sepals glabrous..... *T. seubertiana*

4. Leaf-sheaths margins ciliate to setose; sepals with indumenta..... 5

5. Leaf-blades entirely green; pedicels glabrous; sepals green, setose, with sparse hairs restricted to the keel; petals white; testa costate..... *T. crassula*
5. Leaf-blades abaxially vinous tinted to vinous; pedicels sparsely pilose; sepals vinous, pilose at the apex; petals pink; testa rugose..... *T. valida*
2. Stem creeping to ascending at the apex or fruticose; basal leaves generally evidently subpetiolate, rarely all leaves sessile, blades flat; cincinni bracts saccate at base; pistil the same length as the stamens..... 6
6. Fruticose herbs, stems succulent; petals white to pink; testa rugose, hilum shorter than $\frac{1}{2}$ the length of the seed..... *T. tenella*
6. Non-fruticose herbs, stems herbaceous; petals always white; testa costate, hilum longer than or equal $\frac{1}{2}$ the length of the seed..... 7
7. Leaf-blades always with indumenta on both sides; basal-leaves sessile, secondary veins inconspicuous adaxially; sepals without keels..... 8
8. Leaf-sheaths velutine, margin setose, blades adaxially blueish-green, velutine, hairs hyaline, adpressed; cincinni bracts similar to each other; sepals velutine..... *T. cymbispatha*
8. Leaf-sheaths hirsute, margin densely hirsute, blades adaxially dark-green, hirsute, hairs golden to light-brown, upright; cincinni bracts strongly unequal among each other; sepals glandulous..... *T. chrysophylla*
7. Leaf-blades usually glabrous, rarely with indument on one or both sides of the blade, basal leaves short subpetiolate, secondary veins adaxially impressed; sepals keeled..... 9

9. Stems glabrous; leaf-sheaths glabrous, blades ovate to broadly ovate, rarely elliptic, membranous to slightly succulent, abaxially light-green, glabrous; floral buds ellipsoid, sepals pilose, hairs restricted to the keel, petals plicate..... *T. fluminensis*
9. Stems minutely velutine to velutine; leaf-sheaths minutely velutine to velutine, blades lanceolate to elliptic to broadly elliptic, rarely ovate, chartaceous, abaxially tinted vinous to vinous, minutely velutine to velutine; floral buds ovoid, sepals velutine in fresh material (hairs caducous when dry, generally persistent only along the keel), petals flat..... *T. mundula*

Etymology: The epithet means “*cerinthoides*” means “which looks like pollen grains”, probably making reference to the moniliform hairs of the filaments. These hairs are theorized by Faden (1992) to possess this exact function.

Distribution and habitat: Argentina, Brazil (São Paulo, Paraná, Santa Catarina e Rio Grande do Sul) and Uruguay (Map 2). It can be found in the field formations growing in full sun or in shaded conditions, directly over rock or as a terrestrial plant. It can be also found in sand dunes and *restinga* formations.

Conservation status: Least Concern (LC).

Nomenclatural notes: *Tradescantia blossfeldiana* was described by Mildbraed (1940) based on cultivated material by Blossfeld, from Argentina. Mildbraed gives a complete description that gives us no doubt that this species should be treated as a synonym of *T. cerinthoides*. Nevertheless, he cites no examined material. It is known that Mildbraed worked in Berlin (Stafleu & Cowan 1981) and it's very likely that the original material(s) used in the description is/are deposited at B. Unfortunately, due to the impossibility to personally visit the B herbarium we were unable to solve this mystery and designate a type for this name. Nevertheless, since the description presented on the protologue is extremely detailed, we have no doubt that *T. blossfeldiana* should be treated as a synonym of *T. cerinthoides*.

Tradescantia decora was described by Bull (1892), being characterized by its upright stems and spirally-alternate elongate lanceolate leaves. Despite not being able to analyze the type

specimen, since *T. cerinthoides* is the sole species in *T.* section *Austrotradescantia* which can possess spirally-alternate, we have no doubt *T. decora* should be treated as synonym of the latter.

Taxonomic notes: *Tradescantia cerinthoides* is a highly plastic species, being the sole species in the section where the phyllotaxy can vary in adult individuals. The spirally-alternate individuals of *T. cerinthoides* represent the morphological variation described by Seubert in *T. koernickeana*. It is part of the *T. crassula* group, possessing erect stems, succulent stems and leaves, not saccate cincinni bracts and flowers that vary from white to pink to lilac. It can be easily differentiated from the remaining species of this clade for being the sole species with sepals without keels and homogeneously covered with indumenta (that vary from glandulous to pilose to hirsute). Also, its leaves are generally densely covered by indumenta on the abaxial side, but some individuals with completely glabrous can leaves can also be found.

Tradescantia cerinthoides is the most popular species as pot plant, from the *T. crassula* group. This is due especially due to the beautiful pink to lilac flowers that are common in the cultivated individuals, and the dense leave indumenta.

1.2. *TRADESCANTIA CRASSULA* Link & Otto, Icon. Pl. Rar. 2: 13, pl. 7. 1828 ≡ *Tropitria crassula* (Link & Otto) Raf., Fl. Tell. 3: 68. 1837. *Type*: BRAZIL. Rio Grande do Sul: Rio Pardo, xii.1836, F. Sellow 3033 (**lectotype designated here**: B barcode B 10 0521014!). (Fig. 8)

– *Tradescantia crassipes* Graham, Edinburgh New Philos. J. Jan.–March: 388. 1829, *nom. nud.*

Herbs terrestrial, rupicolous or epiphytes, ca. 10–46 cm tall. **Stem** erect, succulent, little branched, branching at the base, rarely branching at the upper half; internodes (1.3–)3.2–5.4(–9.2) cm long at base, distally shorter, green, glabrous, sometimes with a leaf-opposed longitudinal line of short, uniseriate, light-brown to hyaline hairs in the terminal portion of the stems. **Leaves** distichously-alternate, sessile; sheaths 0.6–2 cm long, light-green, glabrous, margin ciliate to setose, hairs hyaline; blades elliptic to broadly elliptic to ovate to broadly ovate to obovate, rarely lanceolate, 4.4–12.8 × 1.4–2.8 cm, falcate to complicate, succulent, glabrous on both sides, adaxially glossy light-green to green, sometimes glaucous, abaxially slightly lighter, turning olive-green to greyish-green to brown when dry, obtuse to truncate, rarely cuneate, margin green, minutely ciliolate to entire, slightly revolute, apex acute to obtuse, rarely acuminate; midvein conspicuous to inconspicuous, adaxially impressed to inconspicuous, secondary veins inconspicuous on both sides. **Inflorescences** terminal or axillar in the distal portion of the stems, 1 per leaf axis; peduncles (0.3–)1.4–3.6(–7.3) cm long, green, glabrous, sometimes with a leaf-opposed longitudinal line of short, uniseriate, light-brown to hyaline hairs; cincinni bracts similar to each other, rarely reduced in some axillary inflorescences, broadly ovate to ovate, 1.2–3.9(–6) × 0.7–2.1 cm, leaf-like, glabrous, adaxially light-green to green, abaxially slightly lighter, base cordate to obtuse, not saccate, margin entire to minutely ciliolate to sparsely hirsute near the base, apex acute; double

cincinni ca. 8–22-flowered. **Flowers** ca. 0.8–1.2 cm diam., pedicels 0.7–1.5 cm long, green, rarely vinous, glabrous; floral buds broadly ovoid; sepals 4.6–7.5 × 2.7–4.4 mm, dorsally keeled, green, setose, with sparse hyaline hairs restricted to the keel; petals 6–7.3 × 4.7–5.2 mm, flat, white; filaments 5.1–6.6 mm long, anthers ca. 6–8 × 1.1–1.3 mm; ovary 1.7–1.9 × 1.5–1.7 cm, style 4.2–5 cm long; pistil longer than the stamens. **Capsule** 3.6–4.2 × 2.1–2.7 mm. **Seeds** 1.2–1.8 × 1.1–1.6 mm, brown to greyish-brown, testa costate arranged in radiated ridges, hilum longer than $\frac{1}{2}$ the length of the seed.

Examined material: ARGENTINA. **Misiones:** Cainguás, pequeño campo a la entrada del Salto Golondrina, sobre Arroyo Guiray, 8.xi.2000, fl., fr., *M.E. Múlgura de Romero et al.* 2470 (CTES, SI); General Manuel Belgrano, ruta nacional 101, 8 km de Bernardo de Irigoyen hacia San Antonio, Salto Andrecito, 15.x.1996, fl., *O. Eiten et al.* 5998 (SP); Itararé, fazenda Ibiti (Ripasa), beira da estrada Itararé-Bonsucesso, 30.x.1993, fl., fr., *V.C. Souza et al.* 4531 (ESA, RB); São Paulo, Cidade Jardim, 11.iii.1932, fl., fr., *W. Hoehne s.n.* (IPA 69219, SPF 17149). **Etymology:** The epithet “*crassula*” makes reference to the extremely succulent vegetative parts characteristic of this species.

Distribution and habitat: Argentina and Brazil (Minas Gerais, São Paulo, Paraná, Santa Catarina e Rio Grande do Sul) (Map 3). As most species of the *T. crassula* group, *T. crassula* is commonly found growing in field formations, under full sunlight, as rupicolous or terrestrial. Nevertheless, it can also be found at roadsides and understory in open forests.

Conservation status: Least Concern (LC).

Taxonomical notes: *Tradescantia crassula* is very plastic in plant stature, leaf shape and flower size. Nevertheless, all studied individuals always present glabrous leaves, white flowers and sepals with long hairs along the keel. Added to that, most of the known variation can be related to ecological conditions, since specimens with different morphs (more or less succulent plants, smaller or taller plants, plants with different leaf shapes) became very similar in cultivation.

1.3. TRADESCANTIA CHRYSOPHYLLA M.Pell. *sp. nov.*

Tradescantia cymbispathae C.B.Clarke affinis, sed planta omnino aurum hirsuta praesertim in foliis et vagina, sepalis et pedicelli glandulosae.

Type: BRAZIL. São Paulo: Biritiba Mirim, Estação Biológica de Boracéia, 24.xi.1983, fl., A.

Custódio Filho 1910 (holotype: RB!; isotype: SP!). (Fig. 9)

Herbs terrestrial or rupicolous, ca. 11–27 cm tall. **Stem** creeping to ascending at the apex, delicate to slightly succulent, densely branched; internodes 1.5–8.2 cm long at base, distally shorter, hirsute, hairs golden to light-brown. **Leaves** distichously-alternate, sessile; sheaths 0.4–1 cm long, hirsute, margin densely hirsute, hairs golden; blades broadly elliptic to broadly ovate, 1.9–7 × 0.9–2.7 cm, flat, succulent, hirsute on both sides, hairs golden to light-brown, upright, adaxially dark-green, abaxially vinous, turning dark-brown to olive-green when dry, margin cordate to obtuse, ciliolate, apex acute; midvein conspicuous, adaxially impressed, secondary veins inconspicuous, adaxially inconspicuous, abaxially inconspicuous, becoming more evident abaxially when dry. **Inflorescences** terminal or axillar in the distal portion of the stems, 1 leaf axis; peduncles (0.4–)1.1–4.9 cm long, hirsute, hairs golden to light-brown; cincinni bracts strongly unequal among each other, elliptic to ovate to broadly ovate, 0.9–4.6 × 0.4–2 cm, leaf-like, hirsute, hairs golden to light-brown, dark-green, abaxially vinous, base cordate to obtuse, saccate, margin ciliolate, apex acute; double cincinni ca. (4–)6–12-flowered. **Flowers** ca. 1.1–1.6 cm diam., pedicels 0.9–1.2 cm long, glandulous; floral buds ovoid; sepals 4.7–5.8 × 2.6–4 mm, without keels, glandulous; petals 8.8–9 × 5.7–6.2 mm, white; filaments 6–6.2 mm long, anthers ca. 0.6–0.8 × 0.3–0.7 mm; ovary 1.5–1.7 × 1.2–1.4 mm, style 4–4.2 cm long; pistil the same length as the stamens. **Capsule** not seen. **Seeds** not seen.

Examined material (paratypes): BRAZIL. **Rio de Janeiro:** Itatiaia, Serra do Itatiaia, Maromba, 23.x.1931, fl., *C. Porto 2101* (RB). **Santa Catarina:** Rio do Sul, estrada Rio do Sul-Lontras, 3.xii.2013, fl., *A.L. Gasper et al. 3270* (FURB). **São Paulo:** Salesópolis, Estação Biológica de Boracéia, estrada para a barragem da SABESP no rio Guaratuba, 5.ix.1994, fl., *R. Simão-Bianchini et al. 505* (RB, SP, UEC).

Etymology: The epithet “*chrysophylla*” means golden leaves and is given after the golden hairs that cover the whole plant, but especially the leaves.

Distribution and habitat: Endemic to Brazil, more precisely to the states of Rio de Janeiro, São Paulo and Santa Catarina (Map 4). It can be found growing as a terrestrial or rupicolous herb, understory in shaded and moist forests.

Conservation status: Data Deficient (DD).

Taxonomic notes: *Tradescantia chrysophylla* can be differentiated from all the species of *Tradescantia* sect. *Astrotradescantia* by its dense hirsute golden indumenta, which covers the whole plant, especially the leaf sheaths and blades. It is morphologically similar to *T. cymbispatha* due to their sessile, succulent leaves homogeneously covered by indumenta, inconspicuous secondary veins and sepals without keels. Nevertheless, *T. chrysophylla*’s indumenta is hirsute and golden (sometimes becoming light-brown when over exposed to the sun), the cincinni bracts are strongly unequal among themselves, and the pedicels and sepals are covered by glandulous hairs.

1.4. *TRADESCANTIA CYMBISPATHA* C.B.Clarke in De Candolle, Monogr. Phan. 3: 296. 1881 ≡ *Tradescantia cymbispatha* var. *cymbispatha* C.B.Clarke, in De Candolle Monogr. Phan. 3: 296. 1881. Etymology: This names makes clear the great nomenclatural confusion created by Clarke's misinterpretation of Vellozo's plate. The epithet means "boat-shaped bract", a character present only in the Bolivian species from section *Cymbispatha* (*T. praetermissa* M.Pell.) Clarke misused in his description, and not in the real *T. cymbispatha*.

Distribution and habitat: Argentina, Brazil (Rio de Janeiro, Paraná, Santa Catarina e Rio Grande do Sul) and Paraguay (Map 5). It can be found as terrestrial, rupicolous, rarely as an epiphyte, understory in shaded and moist forests.

Conservation status: Least Concern (LC).

Taxonomic notes: In field, *T. cymbispatha* is a very distinctive species being easily differentiated from the remaining species of the *T. fluminensis* group by its adaxially blueish-green, abaxially vinous leaves, which possess a peculiar velvety glow due to its dense villous and appressed hyaline hairs. The stems are prostrated and the populations form dense mats that may cover long areas, which produce a bluish herbaceous formation understory. The sepals are not keeled and homogenously velutine, making it easy to differentiate *T. cymbispatha* from *T. mundula* and *T. fluminensis* (which are part of the *T. fluminensis* morphological complex). Also, *T. cymbispatha* possesses some very interesting characters that become evident when specimens are dried. First, the intense blueish-green pigmentation of the adaxial side becomes dark-brown, while the vinous pigmentation (anthocyanin) evaporates, leaving the abaxial side light-brown. Second, despite no veins being visible in this species leaves due to its succulence; the dried leaves acquire a striate aspect due to the big epidermal domes this species possesses. These two characters are of great taxonomic utility for identifying herbaria specimens of *T. cymbispatha*.

Etymology: The epithet “*fluminensis*” makes reference to the region it was collected, the state of Rio de Janeiro.

Distribution and habitat: Argentina and Brazil (Espírito Santo, Rio de Janeiro, Minas Gerais, São Paulo, Paraná, Santa Catarina e Rio Grande do Sul) (Map 6). It can be found growing as terrestrial or epiphyte understory in shaded moist forests, as a weed and at roadsides.

Conservation status: Least Concern (LC).

Nomenclatural notes: Most of the missing types are assumed to be lost at B herbarium, but due to the impossibility to personally visit the B herbarium we were unable to designate a type for these names. Thus, based on the description presented on these names protogues' and on comments made by Hunt (1980, 2001, pers. comm.), we decided to maintain the previous synonymizations until the types specimens are properly analyzed.

Taxonomic notes: The names *T. fluminensis* has been misapplied for almost all species of *Tradescantia* sect. *Austrotradescantia*, including species from the *T. crassula* group. Here we consider *T. fluminensis* as a much lesser variable entity them accepted by previous authors (Seubert 1871; Clarke 1881; Hunt 1980). *Tradescantia fluminensis* can be differentiated from the remaining species of the *T. fluminensis* group (and from the *T. fluminensis* complex) by its ascending stem apex, slightly succulent to membranous leaves, basally subpetiolate, green on both sides, glabrous, with impressed secondary veins adaxially and pilose sepals, with hairs just along the keel.

1.6. TRADESCANTIA MUNDULA Kunth, Enum. Pl. 4: 83. 1843. \equiv *Tradescantia mundula* Kunth var. *mundula*. *Type*: URUGUAY. Montevideo, xii.1836, fl., F. Sellow 2103 (holotype: B barcode B 10 0247279!). (Fig. 12)

Herbs terrestrial, rupicolous or epiphytes, ca. 8–26(–31) cm tall. **Stem** creeping to ascending at the apex, delicate, densely branched; internodes 1–6.2(–9.3) cm long at base, distally shorter, green to vinous, minutely velutine to velutine, generally with a leaf-opposed longitudinal line of short, uniseriate, hyaline hairs. **Leaves** distichously-alternate, basal leaves subpetiolate; sheaths 0.5–1.2 cm long, green to vinous, minutely velutine to velutine, margin sparsely setose to densely setose, hairs light-brown to hyaline; petiole ca. 0.2–0.5(–1–1.3) cm long to indistinct; blades lanceolate to elliptic to broadly elliptic, rarely ovate, 1.1–6.7(–7.8–13.4) \times 0.6–3.4 cm, flat, chartaceous, adaxially glabrous to sparsely velutine to minutely velutine, abaxially minutely velutine to velutine, rarely glabrous, adaxially glossy green, abaxially tinted vinous to vinous, turning olive-green to brown when dry, base cuneate, rarely obtuse, margin green, minutely ciliolate, slightly revolute, apex acute to acuminate; midvein conspicuous, adaxially impressed, secondary veins conspicuous, adaxially impressed, abaxially inconspicuous, becoming more evident on both sides when dry. **Inflorescences** terminal or axillar in the distal portion of the stems, 1 per leaf axis; peduncles 1.4–5.3(–9.3) cm long, green, glabrous with a dense longitudinal line of short, uniseriate, hyaline hairs; cincinni bracts similar to each other, broadly elliptic to ovate, 2.2–5.3(–8.7–10.6) \times 1–2.1 cm, leaf-like, adaxially glabrous to sparsely velutine to minutely velutine, abaxially tinted vinous to vinous, rarely light-green, minutely velutine to velutine, green, base cordate to obtuse, saccate, margin minutely ciliolate, slightly revolute, apex acute to acuminate; double cincinni ca. 6–8-flowered. **Flowers** ca. 1–1.4 cm diam., pedicels 0.9–1.7 cm long, green to vinous,

glandulous to velutine; floral buds ovoid; sepals $5.1\text{--}7.5 \times 2.4\text{--}4.1$ mm, dorsally keeled, green, velutine, hairs caducous when dry, generally persistent only along the keel; petals $6.3\text{--}7.6 \times 3.8\text{--}5.1$ mm, flat, white; filaments $4.4\text{--}5.6$ mm long, anthers ca. $1\text{--}1.2 \times 0.8\text{--}1$ mm; ovary $1.4\text{--}1.9 \times 1\text{--}1.3$ cm, style $3\text{--}5$ mm long; pistil the same length as the stamens. **Capsule** $2.7\text{--}3.6 \times 2.3\text{--}2.7$ cm. **Seeds** $1\text{--}1.7 \times 0.9\text{--}1.3$ mm, greyish-brown to grey, testa costate arranged in radiated ridges, hilum longer than $\frac{1}{2}$ the length of the seed.

Etymology: The epithet “*mundula*” means adorned, making reference to the velutine stems, leaves and sepals that characterize this species.

Distribution and habitat: Argentina, Brazil (Minas Gerais, São Paulo, Paraná, Santa Catarina e Rio Grande do Sul) and Uruguay (Map 7). It can be found growing as a terrestrial, rupicolous or epiphyte understory in shaded and moist forests and also in open forests.

Conservation status: Least Concern (LC).

Taxonomic notes: *Tradescantia mundula* is a small-sized herb and the smallest species from the section. It is morphologically similar to *T. fluminensis*, especially when specimens are analyzed dried. Nevertheless, *T. mundula* can be differentiated from the latter by its prostrate

habit, inconspicuous secondary veins, abaxially vinous, chartaceous, elliptic leaves and homogeneously velutine sepals. It can be differentiated from *T. cymbispatha* by its subpetiolate basal leaves, adaxially dark-green, chartaceous, glabrous with a plastic glow, elliptic, base cuneate, and keeled sepals.

1.7. TRADESCANTIA SEUBERTIANA M.Pell. *sp. nov.*

Tradescantia crassulae Link & Otto affinis, sed planta alpina, vaginæ et sepali omnino glabrata et petali rosea.

Type: BRAZIL. Santa Catarina: Grão-Pará, Serra do Corvo, 4.x.2014, fl., *M.O.O.Pellegrini et al.* 436 (holotype: RB!; isotypes: MBM!, US!). (Fig. 13)

Herbs rupicolous, ca. 20–40 cm tall. **Stem** erect, succulent, little branched, branching at the base, rarely branching at the upper half; internodes 3.1–6.3 cm long at base, distally shorter, green to reddish-purple to vinous, glaucous, glabrous. **Leaves** distichously-alternate, sessile; sheaths 0.4–1.3 cm long, green to green with vinous striations to vinous, glaucous, glabrous, margin glabrous; blades ovate to broadly ovate, 2.8–7.7 × 0.9–3.2 cm, falcate to complicate, succulent, glabrous, adaxially light-green, glaucous, abaxially slightly lighter to reddish-purple to vinous, glaucous, turning olive-green to light-brown when dry, base cordate to obtuse, rarely cuneate, margin green, entire, slightly revolute, apex acute; midvein conspicuous to inconspicuous, adaxially impressed to inconspicuous, secondary veins inconspicuous on both sides, becoming more evident on both sides when dry. **Inflorescences** terminal or axillar in the distal portion of the stems, 1 per leaf axis; peduncles 1.6–3.7 cm long, green to reddish-purple to vinous, glaucous, glabrous; cincinni bracts similar to each other, ovate to broadly ovate, 0.7–3.3 × 0.4–1.2 cm, leaf-like, glabrous, adaxially light-green, glaucous, abaxially slightly lighter to reddish-purple to vinous, glaucous, base cordate to obtuse, not saccate, margin entire, apex acute; double cincinni ca. 6–14-flowered. **Flowers** ca. 0.8–1 cm diam., pedicels 0.7–1.4 cm long, green to reddish-purple to vinous, glaucous, glabrous; floral buds ellipsoid; sepals 4.8–5.9 × 2.4–4.6 mm, dorsally keeled, green to reddish-purple to vinous, glaucous, glabrous; petals 6.3–7 × 3.2–4.4 mm, pink; filaments 2.8–3.2 mm long,

anthers ca. $0.5\text{--}0.8 \times 1.3\text{--}1.5$ mm; ovary $1\text{--}1.3 \times 0.9\text{--}1.2$ cm, style $4.3\text{--}8.5$ cm long; pistil longer than the stamens. **Capsule** $1.8\text{--}2.6 \times 1.8\text{--}2.2$ cm. **Seeds** $1\text{--}1.2 \times 0.8\text{--}1$ mm, grey to greyish-brown, testa costate in radiated ridges, hilum longer than $\frac{1}{2}$ the length of the seed.

Examined material (paratypes): BRAZIL. Rio Grande do Sul: rio Pelotas, BR-116, km 270, 23.xi.1980, fl., A. Krapovickas & R. Vanni 36870 (CTES); Vacaria, entre Vacaria e Caxias do Sul, 26.x.1961, fl., fr., E. Pereira 6527 (RB); Veranópolis, 10 km S de Veranópolis, fl., J. Lindeman & B. Irgang s.n. (CTES 202947, ICN 8107).

Etymology: This species is named after the prominent German botanist Moritz August Seubert (1818–1878), in appreciation for his extensive contribution to Commelinaceae systematics, especially for his contributions to the knowledge of the Brazilian Commelinaceae and *Tradescantia* sect. *Austrotradescantia*.

Distribution and habitat: It's endemic to the alpine region of Rio Grande do Sul and Santa Catarina, Brazil (Map 8). It can be found growing on wet rock walls, from ca. 700 to 1.800 meters above the sea level.

Conservation status: *Tradescantia seubertiana* is known from only four locations and very small populations and none is inside a conservation unit. Thus, it should be considered Critically Endangered (CR), B2ab(iii,v);D.

Taxonomic notes: *Tradescantia seubertiana* is morphologically similar to *T. crassula* and *T. valida*, being differentiated from them by being completely glabrous plants, which includes the leaf-sheath margin (a very uncommon character in the Commelinaceae), and its alpine habit in wet rock walls. Also it can be differentiated from *T. crassula* by its pink flowers.

1.8. TRADESCANTIA TENELLA Kunth, Enum. Pl. 4: 83. 1843. \equiv *Tradescantia fluminensis* var. *tenella* (Kunth) C.B.Clarke in De Candolle Monogr. Phan. 3: 295. 1881 \equiv *Tradescantia fluminensis* f. *tenella* (Kunth) Voss in Siebert & Voss, Vilm. Blumengärtn. ed. 3 1: 1143. 1895. *Type*: URUGUAY. Montevideo, xii.1836, fl., fr., F. Sellow d2290 (holotype: B barcode B 10 0247280!). (Fig. 14)

= *Tradescantia anagallidea* Seub. in Martius, Fl. bras. 3(1): 249. 1871. *syn. nov. Type*: BRAZIL. s. loc., s. dat., fl., fr., F. Sellow 2801-67 (holotype: B barcode B 10 0247281!).

Herbs terrestrial, rupicolous or epiphytes, ca. 6–48 cm tall. **Stem** fruticose, succulent, densely branched; internodes 1.5–9.2 cm long at base, distally shorter, green to vinous, glandulous to sparsely hirsute to glabrous, with a leaf-opposed longitudinal line of short, uniseriate, hyaline hairs in the terminal portion of the stems. **Leaves** distichously-alternate, subpetiolate; sheaths 0.3–1.3 cm long, green, glabrous to hirsute, margin densely setose, hairs light-brown to hyaline; petiole ca. 0.2–2.4 cm long to indistinct; blades to ovate to broadly ovate, rarely elliptic to lanceolate, (0.5–0.9–)1.5–14.8 × 0.6–3.6 cm, flat, membranous to chartaceous, sparsely hirsute to glabrous, adaxially light-green to green to dark-green, sometimes with a vinous stripe along the midvein, abaxially slightly lighter to vinous, turning olive-green to greyish-green when dry, base cordate to obtuse, rarely cuneate, margin green, minutely ciliolate, apex acute to acuminate; midvein conspicuous, adaxially impressed, secondary veins conspicuous, adaxially impressed, abaxially conspicuous, becoming more evident on both sides when dry. **Inflorescences** terminal or axillar in the distal portion of the stems, 1 per leaf axis; peduncles 1.9–5.3(–9.3) cm long, green to vinous, glabrous with a dense longitudinal line of short, uniseriate, light-brown to hyaline hairs; cincinni bracts strongly unequal among each other, elliptic to ovate to broadly ovate, (0.4–)1–8.1 × 0.3–3.1

cm, leaf-like, glabrous to sparsely hirsute, light-green to green to dark-green, sometimes with a vinous stripe along the midvein, abaxially slightly lighter to vinous, base cordate to obtuse, not saccate, margin minutely ciliolate, apex acute; double cincinni ca. (4–)10–14-flowered.

Flowers ca. 0.4–1.4 cm diam., pedicels 0.5–1.7 cm long, green to vinous, glandulous, rarely glabrous; floral buds ovoid; sepals 3–6.6 × 1.8–2.5 mm, dorsally keeled, green, glandulous to sparsely glandulous, rarely glabrous; petals 6.5–6.8 × 4–5.1 cm, white to pink; filaments 3.8–4.1 mm long, anthers ca. 0.9–1.1 × 1.2–1.8 mm; ovary 1.6–1.8 × 1.1–1.4 cm, style 3.5–3.8 mm long; pistil the same length as the stamens. **Capsule** 2.6–3.6 × 2.2–2.5 cm. **Seeds** 0.9–1.7 × 0.9–1.5 mm, grey to greyish-brown, testa rugose arranged in radiated ridges, hilum shorter than $\frac{1}{2}$ the length of the seed.

Etymology: The epithet “*tenella*” means delicate, small, probably making reference to the small portion available to Kunth to describe the species and its delicate appearance.

Distribution and habitat: Argentina, Brazil (Minas Gerais, Rio de Janeiro, São Paulo, Paraná, Santa Catarina e Rio Grande do Sul) and Uruguay (Map 9). It can be found growing as terrestrial, rupicolous or epiphyte understory in shaded and moist forests, between rocks near waterfalls and in clay ravines.

Conservation status: Least Concern (LC).

Taxonomic notes: *Tradescantia tenella* is the most peculiar species from the *T. fluminensis* clade. Nevertheless, this species possesses fruticose, erect and extremely succulent stems, not saccate cincinni bracts and flowers that vary from pink to white, which would be characteristic of the *T. crassula* group. Thus, *T. tenella* can be confused with species from both clades. *Tradescantia tenella* can be differentiated from the species of the *T. fluminensis* group by its erect and succulent stems, not saccate cincinni bracts and flowers that vary from white to pink. It can be differentiated from the remaining species of the *T. crassula* group by its fruticose habit, cincinni bracts strongly unequal among themselves, small flowers and sepals with glandulous hairs, rarely glabrous.

A great deal of morphological variation is recorded for this species regarding plant stature and leaf size and shape. Since this species is not as common as most species of *Tradescantia* sect. *Astrotradescantia*, we were unable to collect all the different morphs and evaluate the change in their morphology. But since all the other studied species presented changes and the different morphs became similar in cultivation, we believe same is true for *T. tenella*.

1.9. TRADESCANTIA UMBRACULIFERA Hand.-Mazz., Denkschr. Kaiserl. Akad. Wiss., Wien. Math.-Naturwiss. Kl. 79: 204. 1908. *Type*: BRAZIL. São Paulo: Campinas, i.1900, fl., *J. Campos Novaes* 1218 (**lectotype designated here**: WU N° 0061328!; isolectotype US barcode US 00046114!). (Fig. 15)

= *Tradescantia fluminensis* var. *pubescens* C.B.Clarke in De Candolle, Monogr. Phan. 3: 295. 1881, *syn. nov.* *Type*: BRAZIL. Provincia de St. Paul and Rio, South Brazil, 1861-1862, fl., *J. Weir s.n.* (**lectotype designated here**: K barcode K 000363269!).

Herbs terrestrial, rupicolous or epiphytes, ca. 25–60 cm tall. **Stem** creeping to ascending at the apex, slightly succulent to slightly fibrous, little to densely branched; internodes 2.8–10 cm long at base, distally shorter, green to reddish-purple to vinous, glabrous to sparsely pilose, with a leaf-opposed longitudinal line of short, uniseriate, light-brown to hyaline hairs in the terminal portion of the stems. **Leaves** distichously-alternate, sessile; sheaths 0.5–2.3 cm long, green to reddish-purple to vinous, glabrous to pilose to sparsely hirsute, margin densely setose, hairs light-brown to hyaline; blades linear-lanceolate to lanceolate, 3.8–19.1 × 1–3.1 cm, flat, chartaceous, rarely membranous, glabrous on both sides to adaxially glabrous, abaxially velutine to pilose, hairs hyaline, adaxially glossy dark-green, abaxially slightly lighter, rarely vinous tinted to completely vinous, turning dark-brown to black when dry, base truncate to amplexicaulous to obtuse, margin green, minutely ciliolate to ciliolate, apex acuminate; midvein conspicuous, adaxially impressed, secondary veins conspicuous, adaxially slightly impressed to impressed, abaxially prominent, becoming more evident on both sides when dry. **Inflorescences** terminal or axillar in the distal portion of the stems, 1–3 per leaf axis; peduncles 0.5–4.3 cm long, green, pilose to glabrous with a dense longitudinal line of short, uniseriate, light-brown to hyaline hairs; cincinni bracts similar to

each other, cordate to broadly cordate, rarely lanceolate, $0.5\text{--}1.2(2.3\text{--}6.2) \times 0.5\text{--}1(1.4)$ cm, spathaceous, rarely leaf-like, glabrous to pilose to sparsely hirsute, green to dark-green, abaxially slightly lighter at the base, base cordate to obtuse, saccate, margin minutely ciliolate to ciliolate, apex acute, rarely acuminate; double cincinni ca. (4-)8-12-flowered. **Flowers** ca. 1.3-2.2 cm diam., pedicels 0.5-1.2 mm long, white to vinous, rarely green, sparsely glandulous; floral buds ellipsoid; sepals $5.2\text{--}8.1 \times 2\text{--}3.7$ mm, dorsally keeled, green, pilose along the keel, with hairs gathered at the base in the insertion of the pedicel, rarely glabrous; petals $0.8\text{--}1.2 \times 0.3\text{--}0.6$ cm, white; filaments 5.7-6.8 mm long, anthers ca. $0.8\text{--}1 \times 0.9\text{--}1.2$ mm; ovary $1.2\text{--}2 \times 0.8\text{--}1.3$ mm, style 4.8-6.2 mm long; pistil longer than the stamens. **Capsule** $2.7\text{--}3.8 \times 2.1\text{--}2.5$ cm. **Seeds** $1.6\text{--}1.9 \times 1.2\text{--}1.5$ mm, greyish-brown, testa costate arranged in radiated ridges, hilum longer than $\frac{1}{2}$ the length of the seed.

Etymology: The epithet “*umbraculifera*” means “with umbrellas”, making reference to the many inflorescences this species generally produces, and most importantly, to the small spathaceous cincinni bract that is characteristic of it.

Distribution and habitat: Argentina and Brazil (Minas Gerais, Rio de Janeiro, São Paulo, Paraná, Santa Catarina e Rio Grande do Sul) and Paraguay (Map 10). It can be found growing as terrestrial and epiphyte understory in shaded and moist forests.

Conservation status: Least Concern (LC).

Nomenclatural notes: When describing *T. umbraculifera*, Handel-Mazzetti (1908) cites the material “Campinas (leg. *Campos Novaes*)”, but cites no collection number or the herbarium where the type is located. According to Stafleu & Cowan (1981), Handel-Mazzetti’s specimens can be found in the WU herbarium, the author’s institution. Nevertheless, since a duplicate of this material was found in the US herbarium, a lectotypification is necessary. Thus, we designate the specimen at WU as the lectotype.

In the protologue of *T. fluminensis* var. *pubescens*, Clarke (1881) lists three specimens: “Rio: in sylvis (*Gaudichaud* n. 1794; *J. Weir*)” and “St-Gabriel (*Aug. de St-Hilaire* n. 44)”. Since Clarke’s research were done on the Royal Botanical Gardens, Kew (Stafleu & Cowan 1981),

the specimen “*J. Weir s.n.*”, deposited in K, seem to be the best choice for an lectotype.

Added to this, the specimen matches the diagnosis provided on the protologue by the author.

Taxonomic notes: *Tradescantia umbraculifera* is the most peculiar species in the whole section *Austrotradescantia*, because of its spathaceous cincinni bracts and numerous inflorescences per leaf axis. These two characters tell this species apart from all the other species of the section. Added to that, when dried, specimens of *T. umbraculifera* acquire a peculiar dark-brown to black color, which is unique in the group. Nevertheless, young individuals of *T. umbraculifera* are sometimes confused with *T. fluminensis*, since they don't possess them numerous inflorescences. Also, it is rather commonly confused with *T. crassula* and is due to the robust habit of both species.

1.10. TRADESCANTIA VALIDA G.Brückn., Notizbl. Bot. Gart. Berlin–Dahlem 11: 510. 1932.

Type: BOLIVIA [BRAZIL]: cult. in Hort. Bot. Münster/W., 28.iv.1932, fl., s. leg. s.n.
(holotype: B barcode B 10 0296487!). (Fig. 16)

Herbs terrestrial or rupicolous, ca. 50–70 cm tall. **Stem** erect, succulent, little branched, branching at the base, rarely branching at the upper half; internodes 1.8–7 cm long at base, distally shorter, green with vertical reddish-purple striations to reddish-purple with green striations, glabrous. **Leaves** distichously-alternate, sessile; sheaths 0.4–0.8 cm long, green to vinous, glabrous, margin ciliolate, hairs hyaline; blades elliptic to broadly elliptic to ovate, 2.7–9 × 1.1–2.5 cm, falcate to complicate, succulent, glabrous, adaxially light-green, abaxially vinous tinted to vinous, turning olive-green to light-brown when dry, base cordate to obtuse, margin vinous, ciliolate, slightly revolute, apex acute; midvein conspicuous to inconspicuous, adaxially inconspicuous, secondary veins inconspicuous, adaxially inconspicuous, abaxially inconspicuous, becoming more evident on both sides when dry. **Inflorescences** terminal or axillar in the distal portion of the stems, 1 per leaf axis; peduncles 3.5–5.2 cm long, green, glabrous; cincinni bracts similar to each other, broadly ovate to ovate, 1.6–3.5 × 0.4–1.2 cm, leaf-like, glabrous, light-green, abaxially slightly lighter, base cordate to obtuse, not saccate, margin minutely ciliolate, apex acute; double cincinni ca. 10–16-flowered. **Flowers** ca. 1–1.2 cm diam., pedicels 1–2 cm long, vinous, sparsely pilose; floral buds ellipsoid; sepals ca. 5–6 × 1.5–3 mm, vinous, dorsally keeled, pilose at the apex; petals ca. 5–6 × 3–4 cm, pink; filaments ca. 4–5 mm long, anthers ca. 0.8–1 × 1–1.2 mm; ovary ca. 1–1.5 × 1–1.3 cm, style ca. 5 mm long; pistil longer than the stamens. **Capsule** ca. 3–4 × 2–3 cm. **Seeds** ca. 2–3 × 1–1.5 mm, brownish to greyish-brown, testa rugose arranged in radiated ridges, hilum longer than $\frac{1}{2}$ the length of the seed.

Examined material: BOLIVIA. Beni: Provincia de Ballivia, lower slopes of Serrania Pilon Lajas, 14.3 km N of the bridge over the Río Quiquibey, 10.vi.1985, fl., J.C. Solomon 13916 (LPB, MO, NY, US).

Etymology: The epithet “*valida*” means erect, stiff, making reference to the plants’ posture and succulent stem.

Distribution and habitat: *Tradescantia valida* was described based on cultivated material, supposedly from Brazil (Brückner 1932). Nevertheless, we found no Brazilian specimen that matched the species protologue and the morphology of the holotype. Added to that, the only other collection known from this species is for the Ballivia, Beni, Bolivia. We believe it is possible that a confusion regarding the origin of this specimen may have occurred. Thus, *Tradescantia valida* is endemic to Bolivia (Map 11). It can be found growing as rupicolous or in shallow sandy and rocky soils in open areas or understory in Bosque Boliviano.

Conservation status: Data Deficient (DD).

Taxonomic notes: *Tradescantia valida* is similar to *T. seubertiana* due to their glabrous, abaxially vinous leaves, vinous pedicels and pink flowers. However *T. valida* can be differentiated from *T. seubertiana* by its ciliate leaf-sheath margins and pilose sepals. Also, the two species grow considerably apart, *T. valida* being native from Bolivia and *T. seubertiana* being endemic to the alpine region of Santa Catarina, Brazil.

ACKNOWLEDGEMENTS

The authors would like to thank CAPES and CNPq for the award of fellowships. We thank the curators and staff of the visited herbaria for the specimens loaned to RB, and for sending high-quality images. Luana Silva Braucks Calazans, Fernanda Santos-Silva, Rafael Felipe de Almeida for suggestions on an early version of the manuscript. We also thank Rafael Felipe

de Almeida for helping editing the images and the maps, Luis A. Funez and Herison Medeiros for sending field photos of the *Tradescantia umbraculifera*. This study was carried out as part of a Master's degree in Biodiversity and Evolutionary Biology by Marco Octávio de Oliveira Pellegrini at Programa de Pós-Graduação em Biodiversidade e Biologia Evolutiva, Instituto de Biologia, Universidade Federal do Rio de Janeiro — IB/UFRJ.

<i>Callisia warszewicziana</i> (Kunth & Bouché) D.R.Hunt	Section <i>Hadrodemas</i>	O. Campos Góes 167 (RB)
<i>Tripogandra brasiliensis</i> Handlos	—	G. Eiten 4458 (SP)
<i>Tripogandra diuretica</i> (Mart.) Handlos	—	M.O.O. Pellegrini 4 (RFA)
<i>Tripogandra elata</i> D.R.Hunt	—	C.A. Fereira Junior s.n. (RB 588051)
<i>Tripogandra glandulosa</i> (Seub.) Rohweder	—	M.O.O. Pellegrini 298 (RB)
<i>Tripogandra purpurascens</i> (Schauer) Handlos	—	J.P. Souza 7579 (ESA)
<i>Tripogandra warmingiana</i> (Seub.) Handlos	—	M.O.O. Pellegrini 223 (RB)

Table 2. Primary literature sources for information used in the phylogenetic analysis.

Character	Source
Pollen	Poole & Hunt 1980 Anderson & Sax 1936; Jones & Jopling
Cytology	1972; Jones, Kenton & Hunt 1981; Martínez 1984; Martínez & Ginzo 1985; Jones 1990
Phytochemistry	Martínez & Sawin 1985; Martínez & Martínez 1993

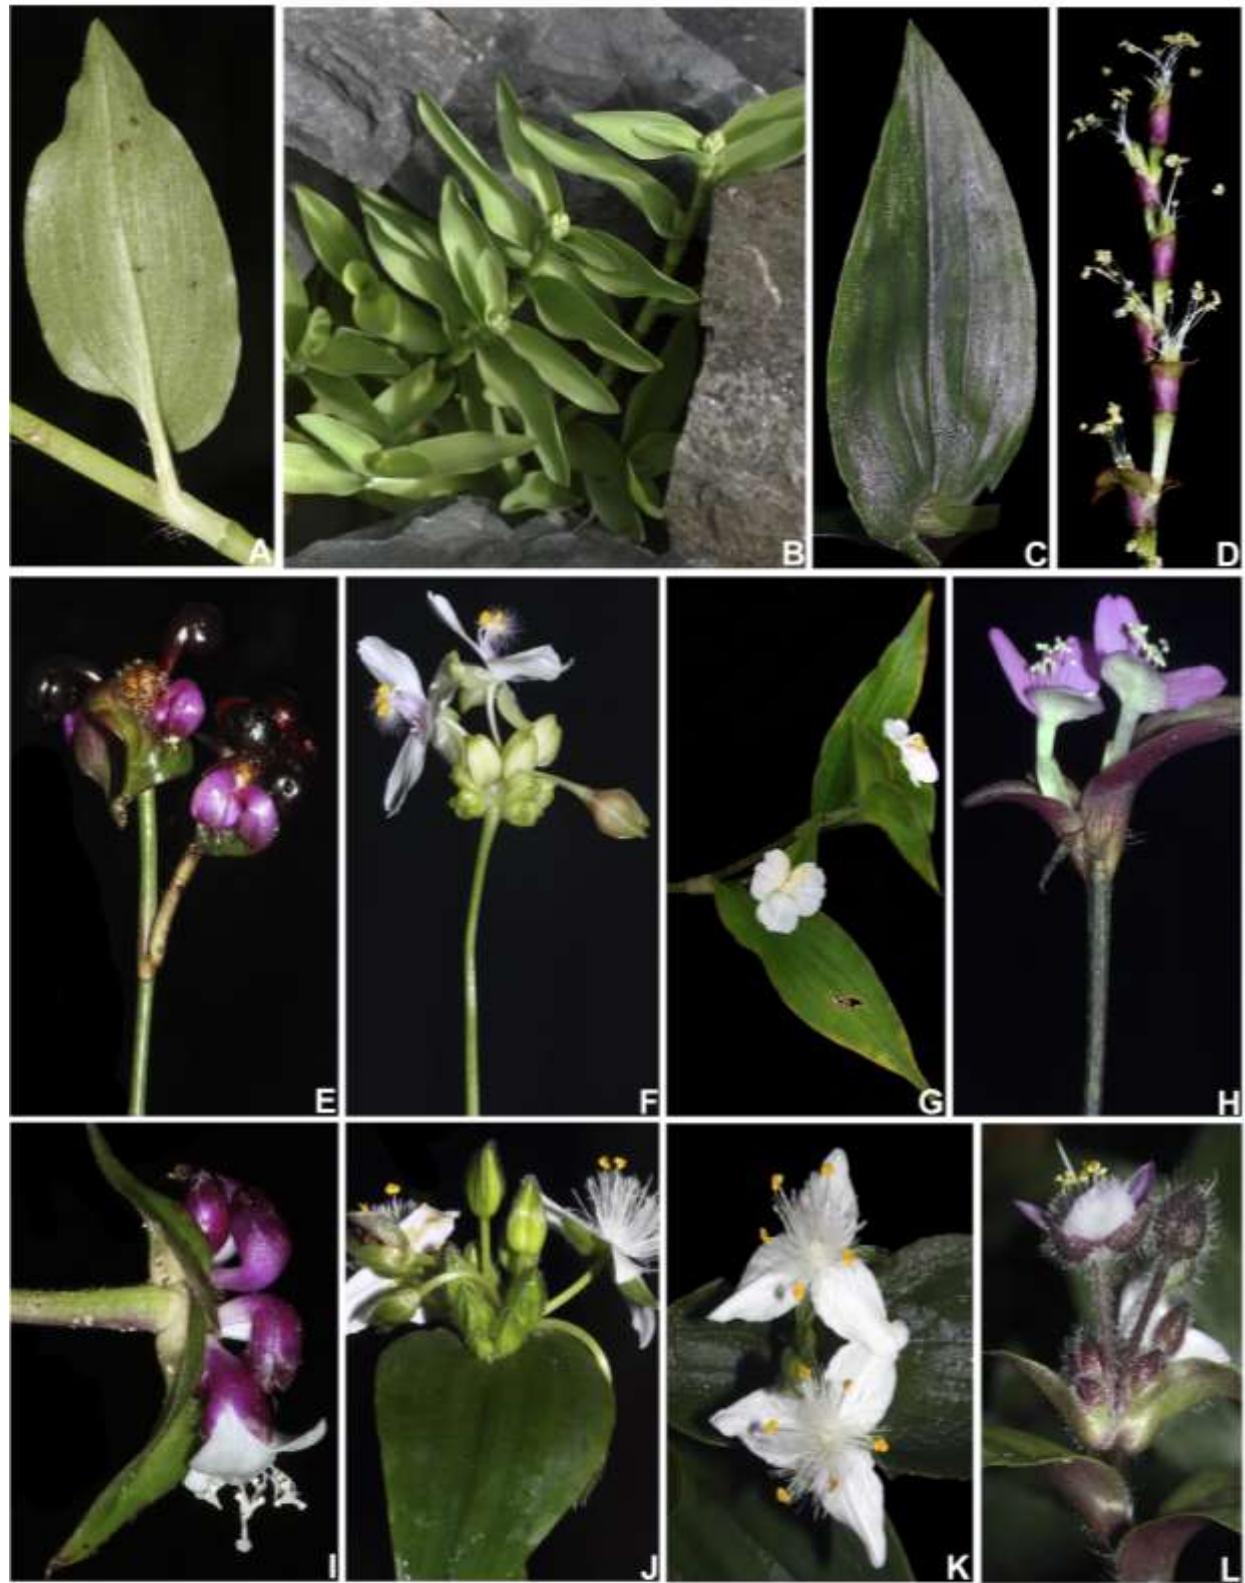

Fig. 1. Morphological characters used in the phylogenetic analysis. **A**, Subpetiolate leaf (Character 6) and asymmetrical base (Character 16) in *Tradescantia tenella*. **B**, Complicate leaves (Character 8) in *Tradescantia crassula*. **C**, Impressed secondary veins (Character 18) in *Tradescantia fluminensis*. **D**, Predominantly axillar to spike-like sinforescence (Character 21) in *Callisia repens*. **E**, Sinforescence with two paraclades (Character 22) in *Tradescantia zanonia*. **F**, Cincinni fused back-to-back (Character 27), contracted cincinni (Character 30), fused cincinni (Character 31), vestigial cincinni bracts (Character 34), flower display of 60° (Character 41), shorter opposite-sepal stamens (Character 61), sigmoid filaments (Character 62), and zygomorphic androecium (Character 64) in *Tripogandra diuretica*. **G**, Present supernumerary cincinni bracts (Character 33) in *Tradescantia praetermissa*. **H**, Cincinni bracts saccate at base (Character 37), tubular flower (Character 40), fused petals (Character 51), clawed petals (Character 53), shorter opposite-sepal stamens (Character 61), connective transversally-linear (Characters 65–66), round anther sacs (Characters 67–68), pollen white colored (Character 69), and trilobed stigma (Character 73) in *Tradescantia zebrina*. **I**, Tubular flower (Character 40), flowers geniculate at anthesis and pre-anthesis (Character 43), fused sepals (Character 44), filaments bearded with sparse and short hairs (Characters 57, 59), shorter opposite-sepal stamens (Character 61), connective transversally-linear (Characters 65–66), round anther sacs (Characters 67–68), pollen white (Character 69), and trilobed stigma (Character 73) in *T. zanonia*. **J**, Keeled sepals (Character 47) in *Tradescantia fluminensis*. **K**, Filaments bearded with dense and long hairs (Characters 57, 59), basal filaments hairs (Characters 58, 60), connective rhomboid (Characters 65–66), ellipsoid anther sacs (Characters 67–68), and pollen yellow (Character 69) in *T. fluminensis*. **L**, Pistil longer than the androecium (Character 71) and punctate (Character 73) in *Tradescantia cerinthoides*. All photos by M.O.O. Pellegrini, except G by H. Huaylla.

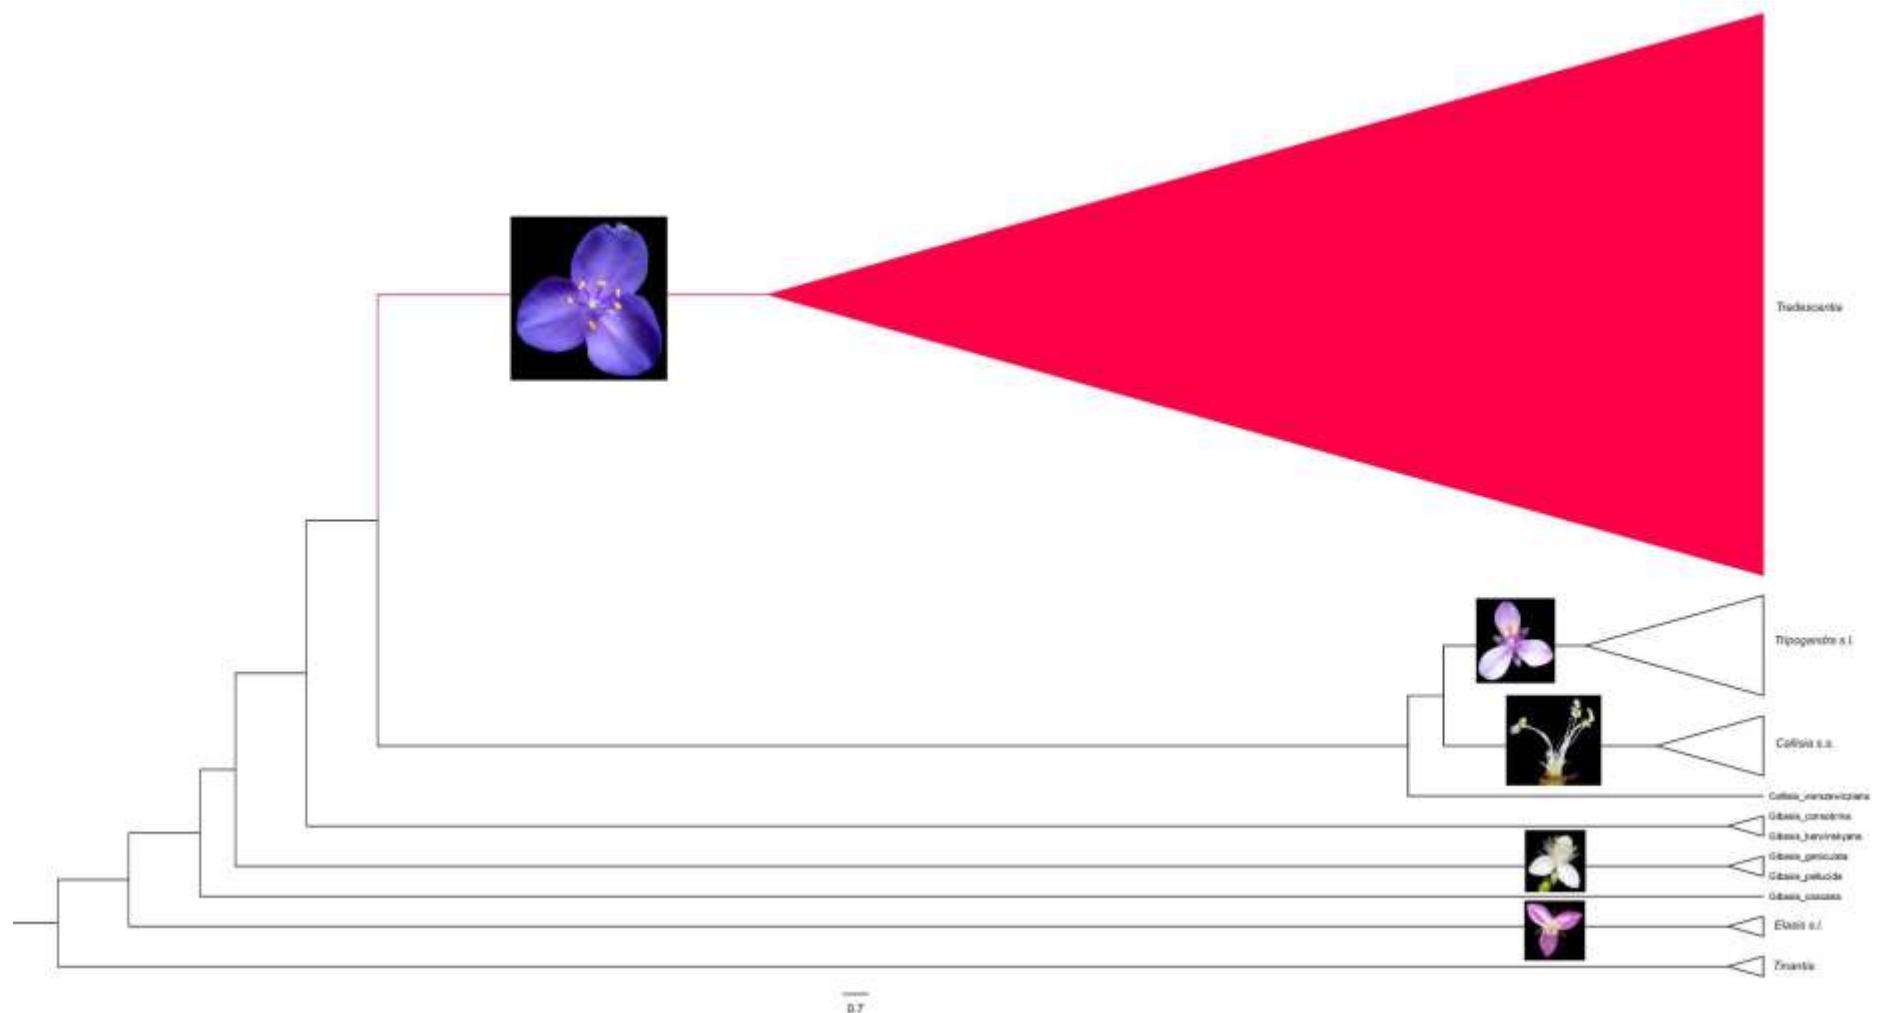

Fig. 2. Majority rule showing the relation between the genera in Tradescantiinae and their floral morphology. *Tradescantia* s.s. is depicted in red.

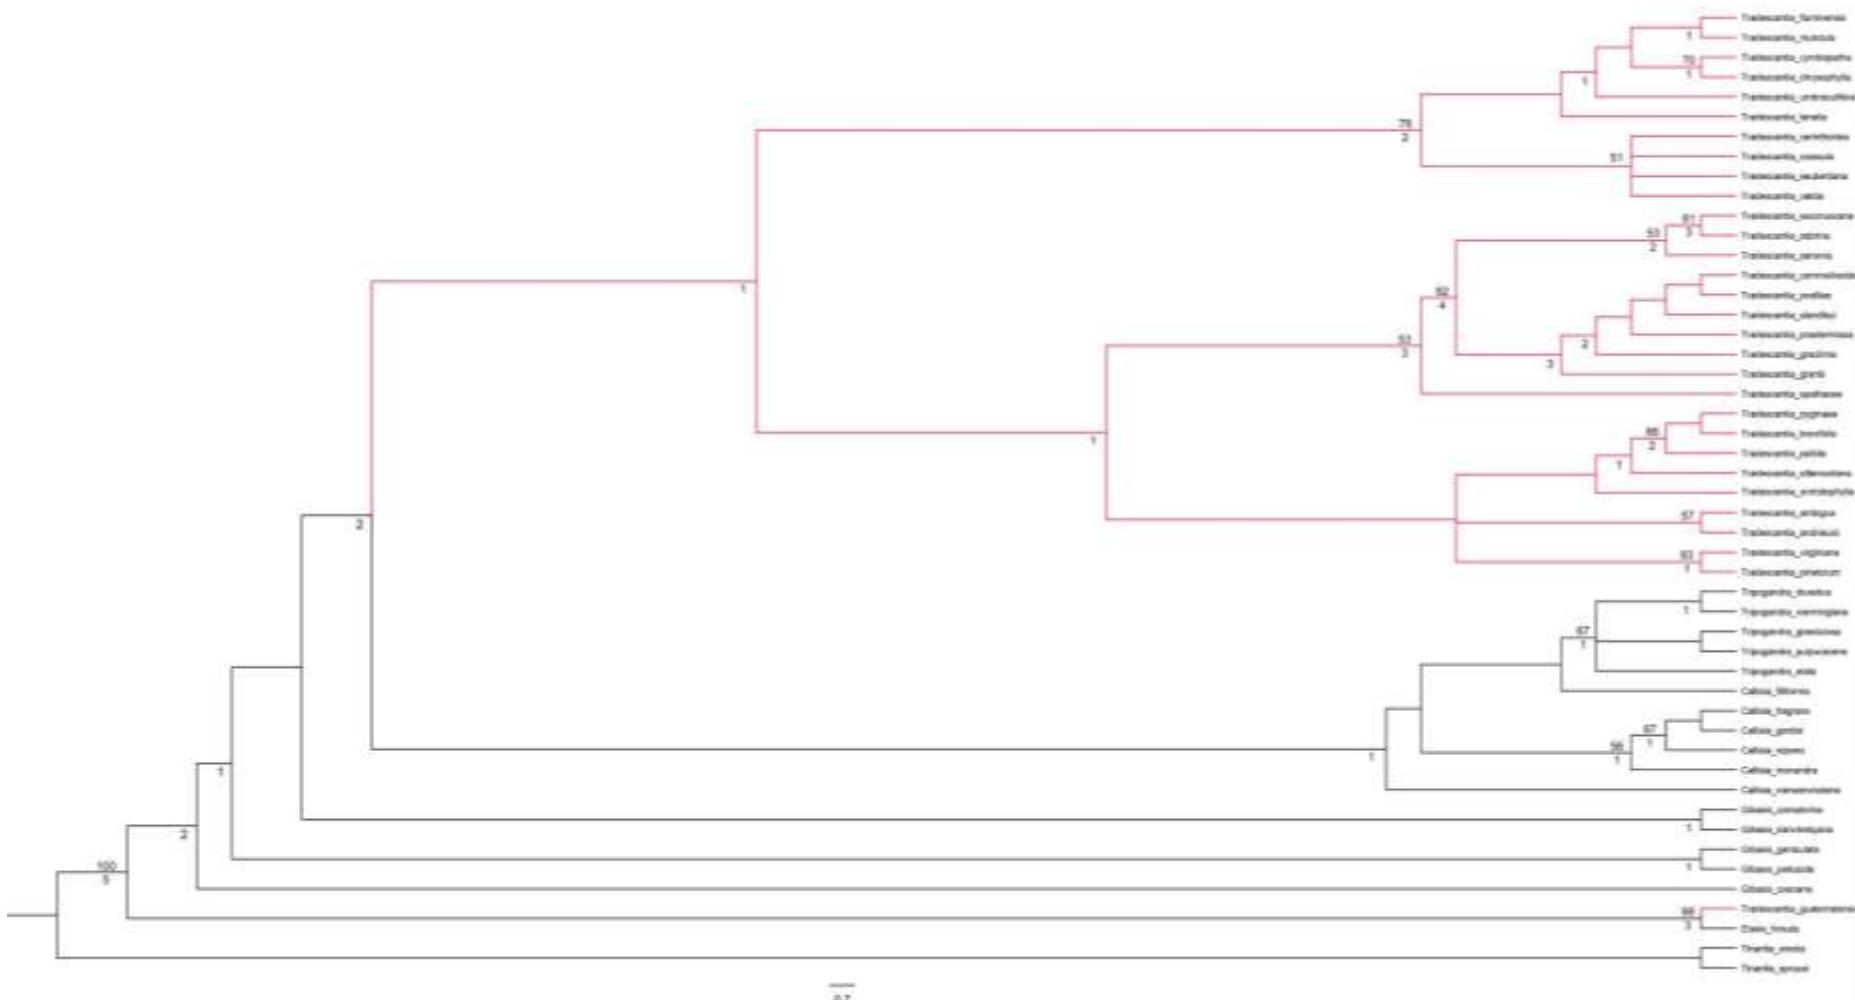

Fig. 3. Majority rule tree from the maximum parsimony analysis (length= 424 steps; CI= 0.3066; RI= 0.7042). The numbers above the branches correspond to the values of BS (≥ 50), and numbers below to the values of BI. *Tradescantia* s.l. (*T. guatemalensis*) is depicted in red.

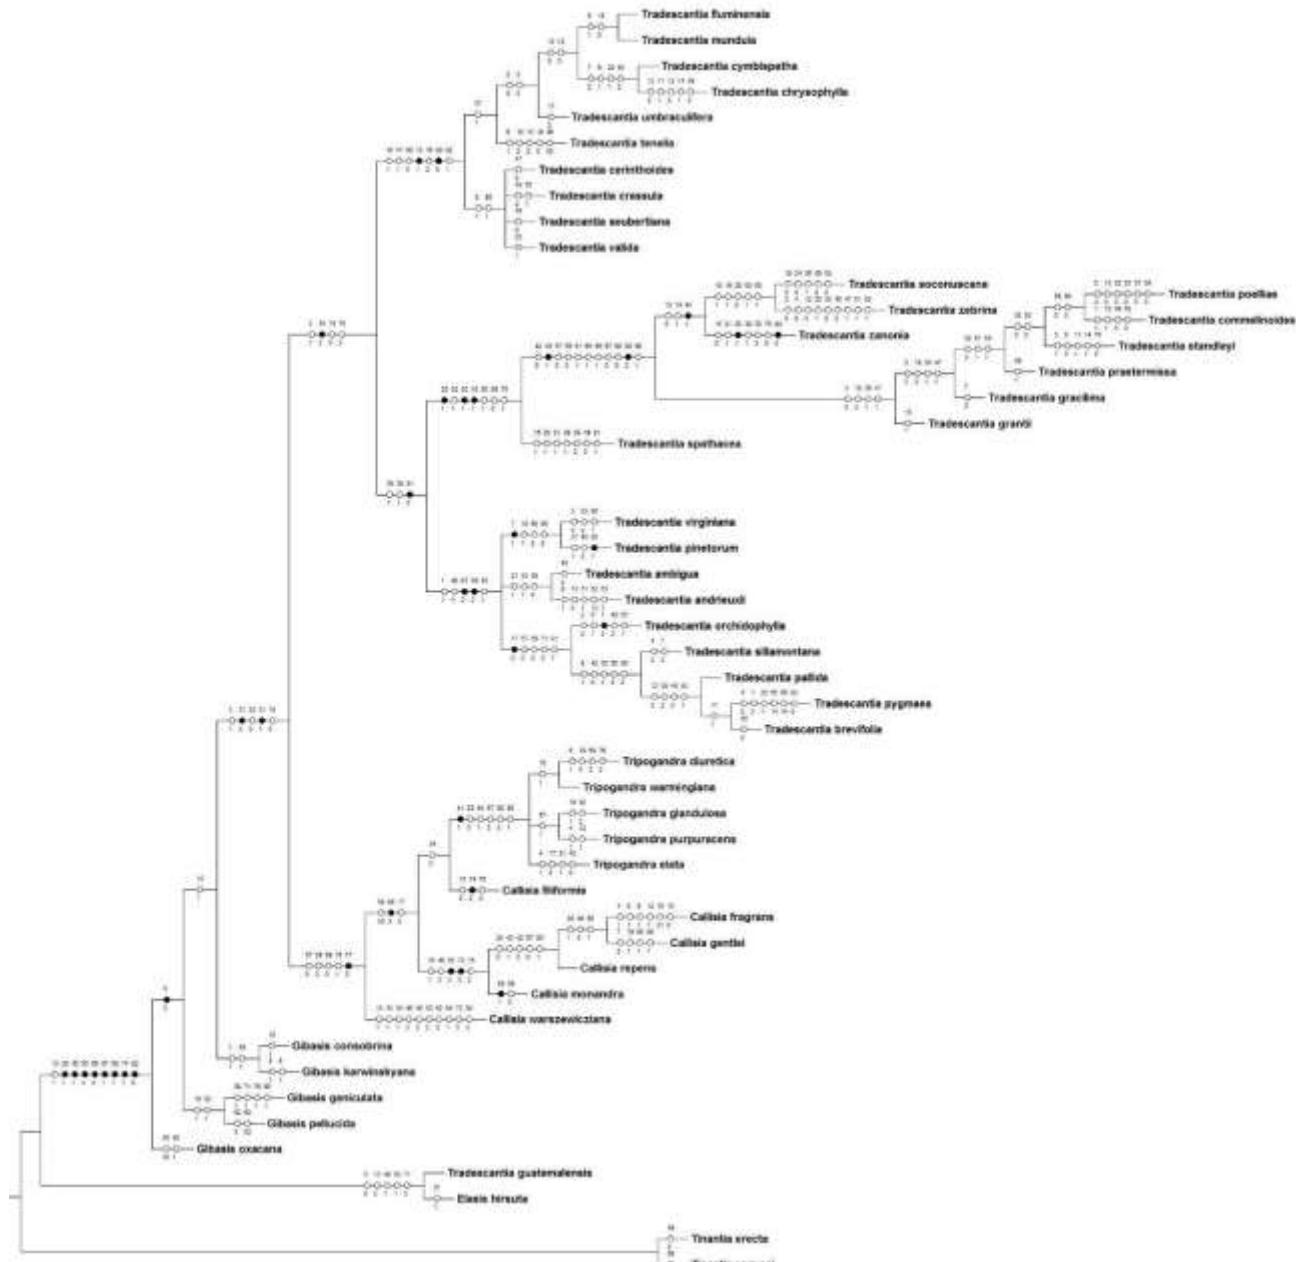

Fig. 4. Majority rule tree showing the character state optimizations at each node of the cladogram, represented by circles. In each circle, the numbers above and below represent the character and character state numbers, respectively (as reported in Supplement).

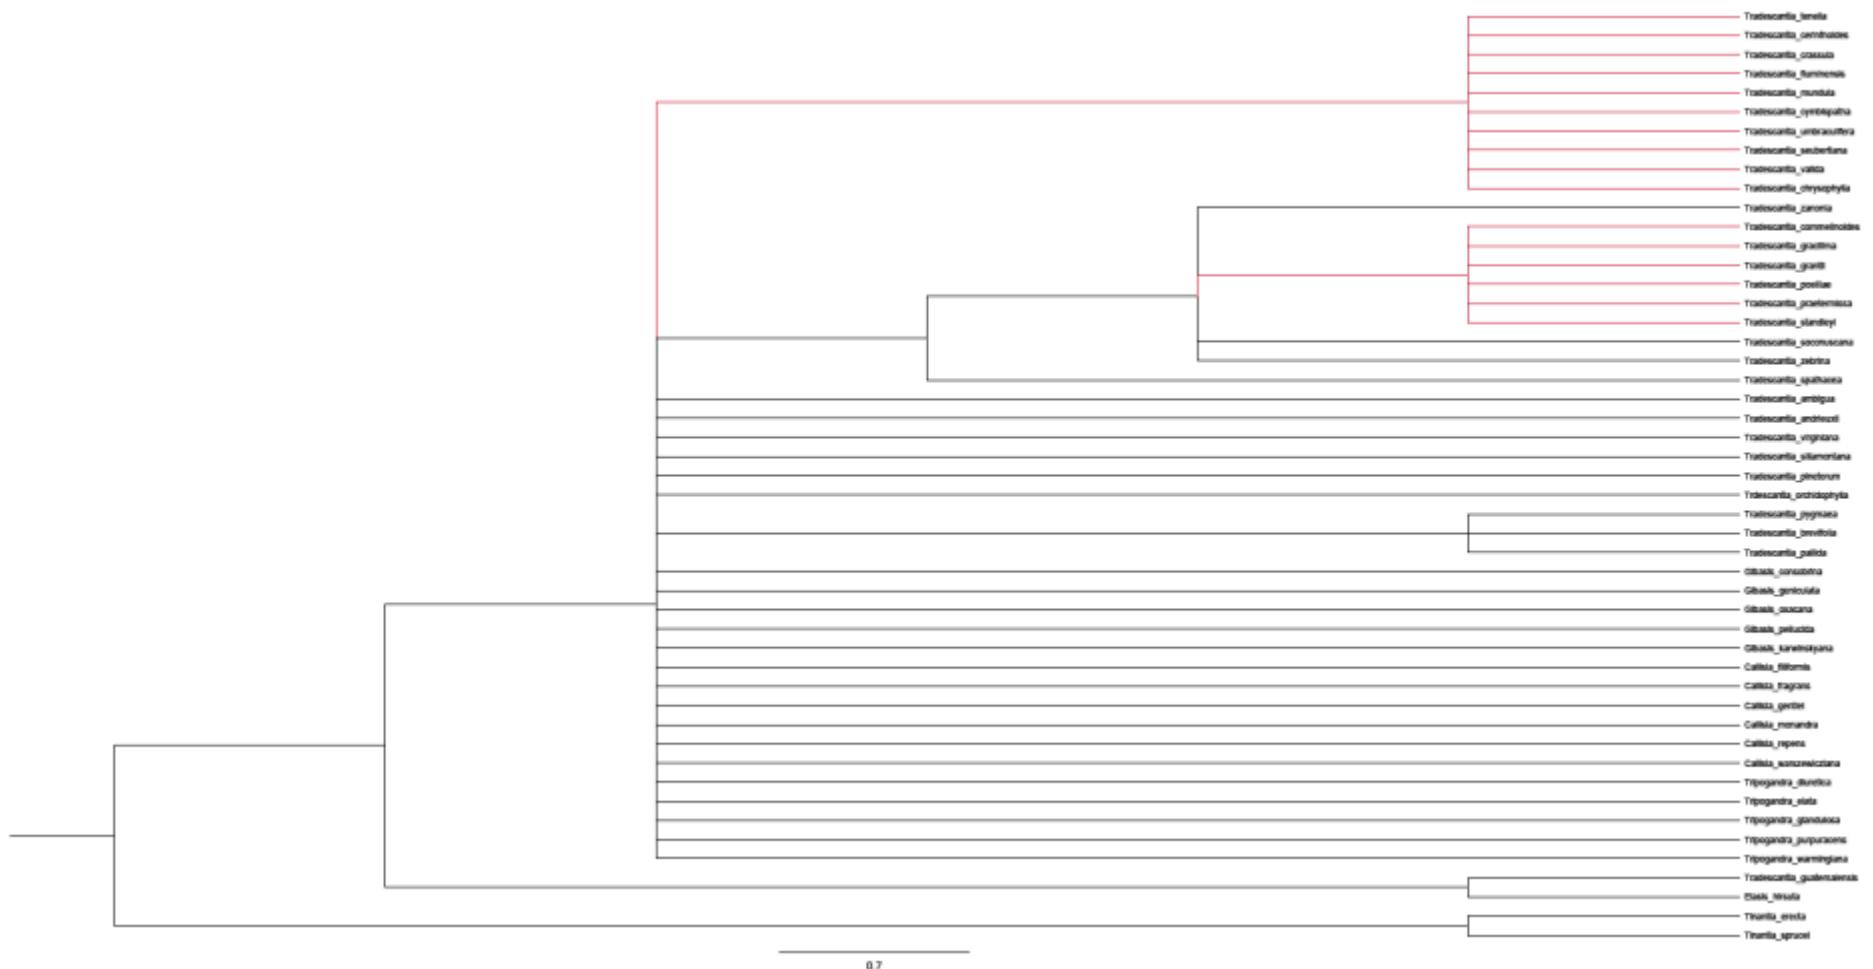

Fig. 5. Strict consensus tree. *Tradescantia* sections *Austrotradescantia* and *Cymbispatha* are depicted in red.

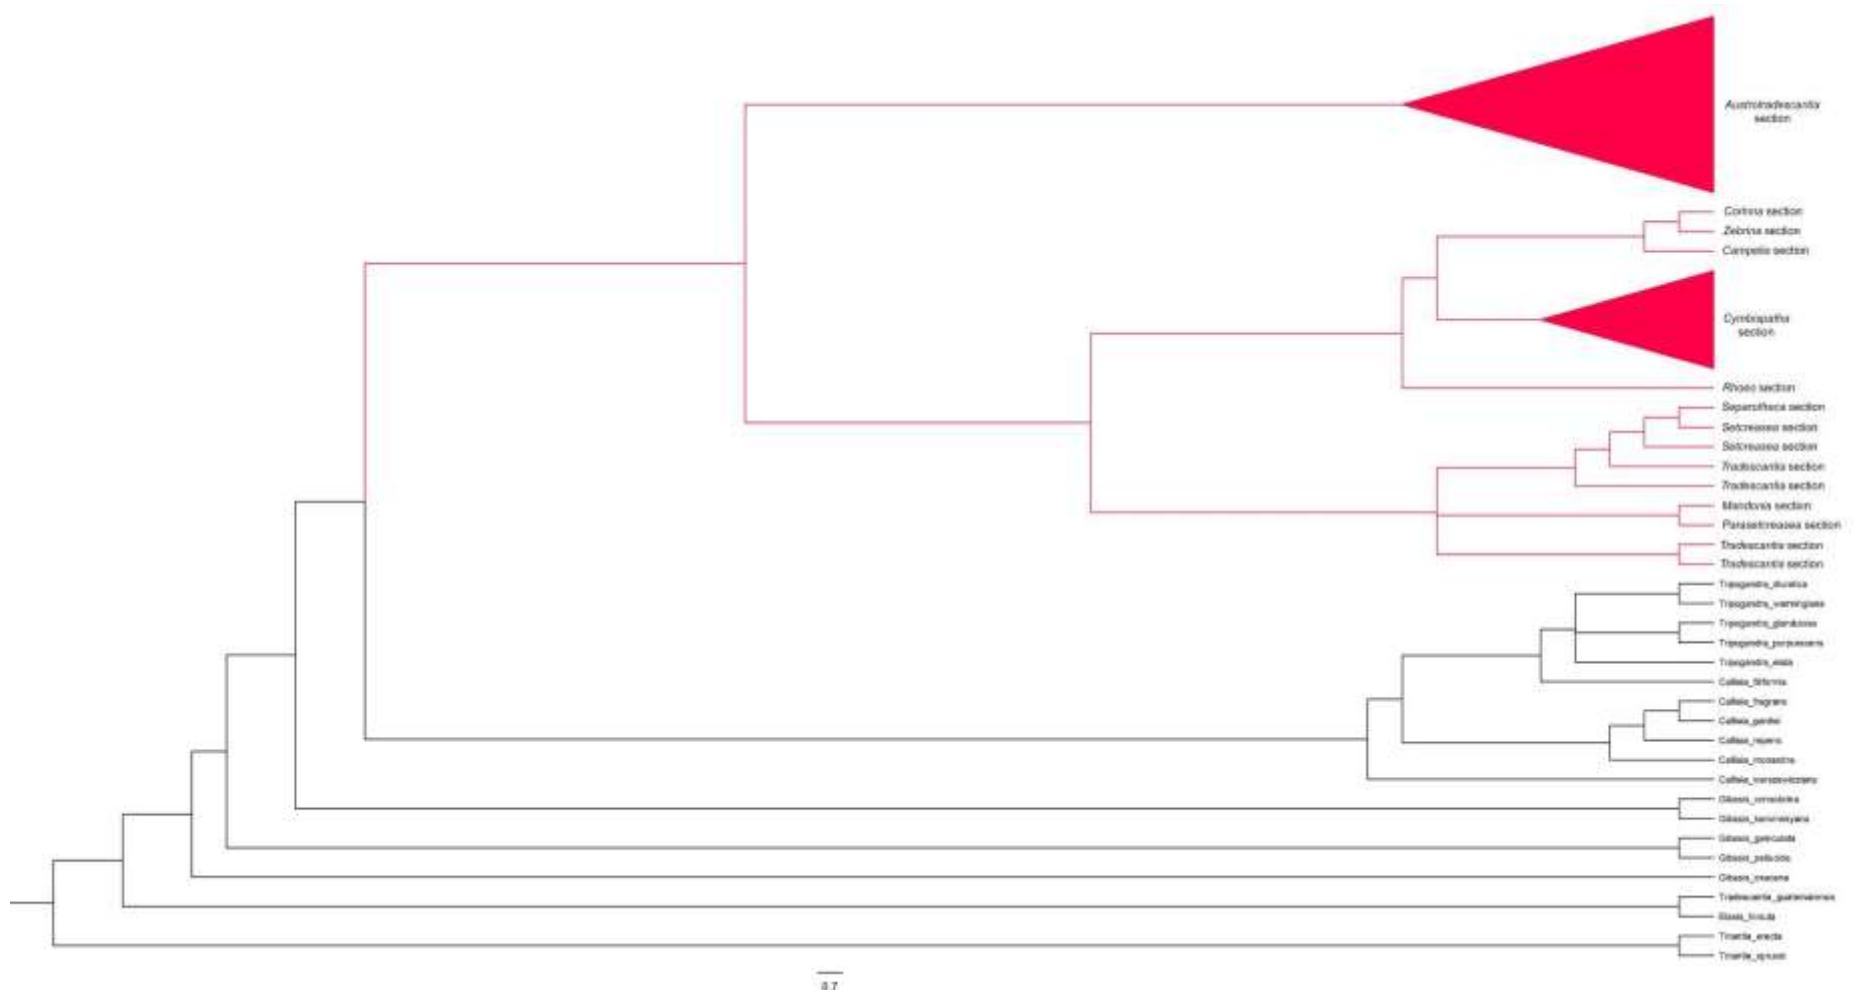

Fig. 6. Majority rule tree showing the sectional classification of *Tradescantia*. *Tradescantia* s.s. is depicted in red and sections *Austrotradescantia* and *Cymbispatha* are collapsed.

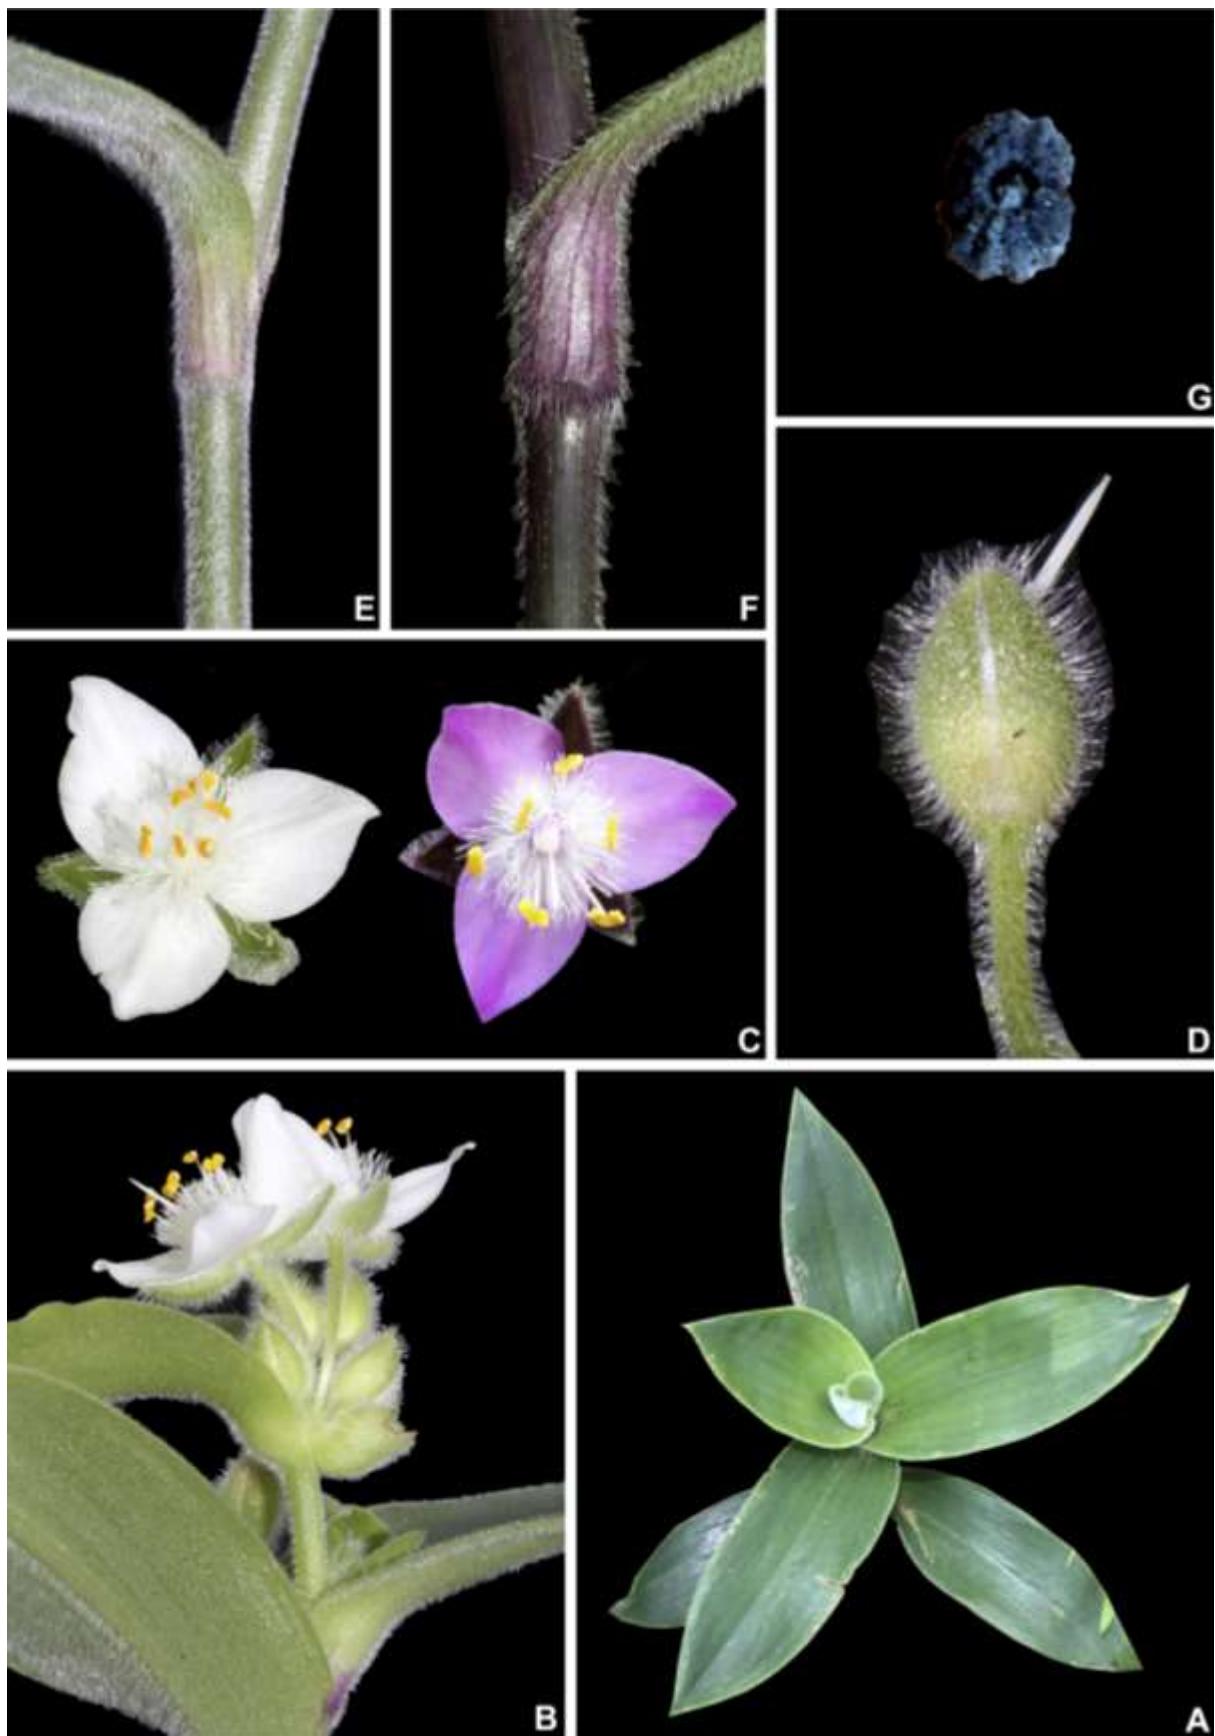

Fig. 7. *Tradescantia cerinthoides* Kunth. **A**, habit. **B**, detail of the inflorescence, showing the not saccate cincinni bract base, and side view of the flower, showing the pistil longer than the androecium. **C**, flowers, showing the petal color variation form white to lilac. **D**, detail of flower at post-anthesis, showing the pedicel's and sepals' velutine indumenta. **E--F**, detail of the stem and leaf-sheath, showing the variation in color and indumenta: **E**, green stem, pinkish leaf-sheath, with velutine indumenta; **F**, vinous stem, vinous leaf-sheath, with hirsute indumenta. **G**, seed, showing the costate testa and dorsal embryotega. Field photos by M.O.O. Pellegrini.

Fig. 8. *Tradescantia crassula* Link & Otto. **A**, habit, showing the erect stems and complicate leaves. **B**, detail of the stem and leaf-sheath. **C**, blade abaxial view. **D**, detail of floral buds, showing the sepals' indumenta restricted to the keels. **E**, flower. **F**, detail of the inflorescence, showing the not saccate cincinni bract base. Field photos by M.O.O. Pellegrini.

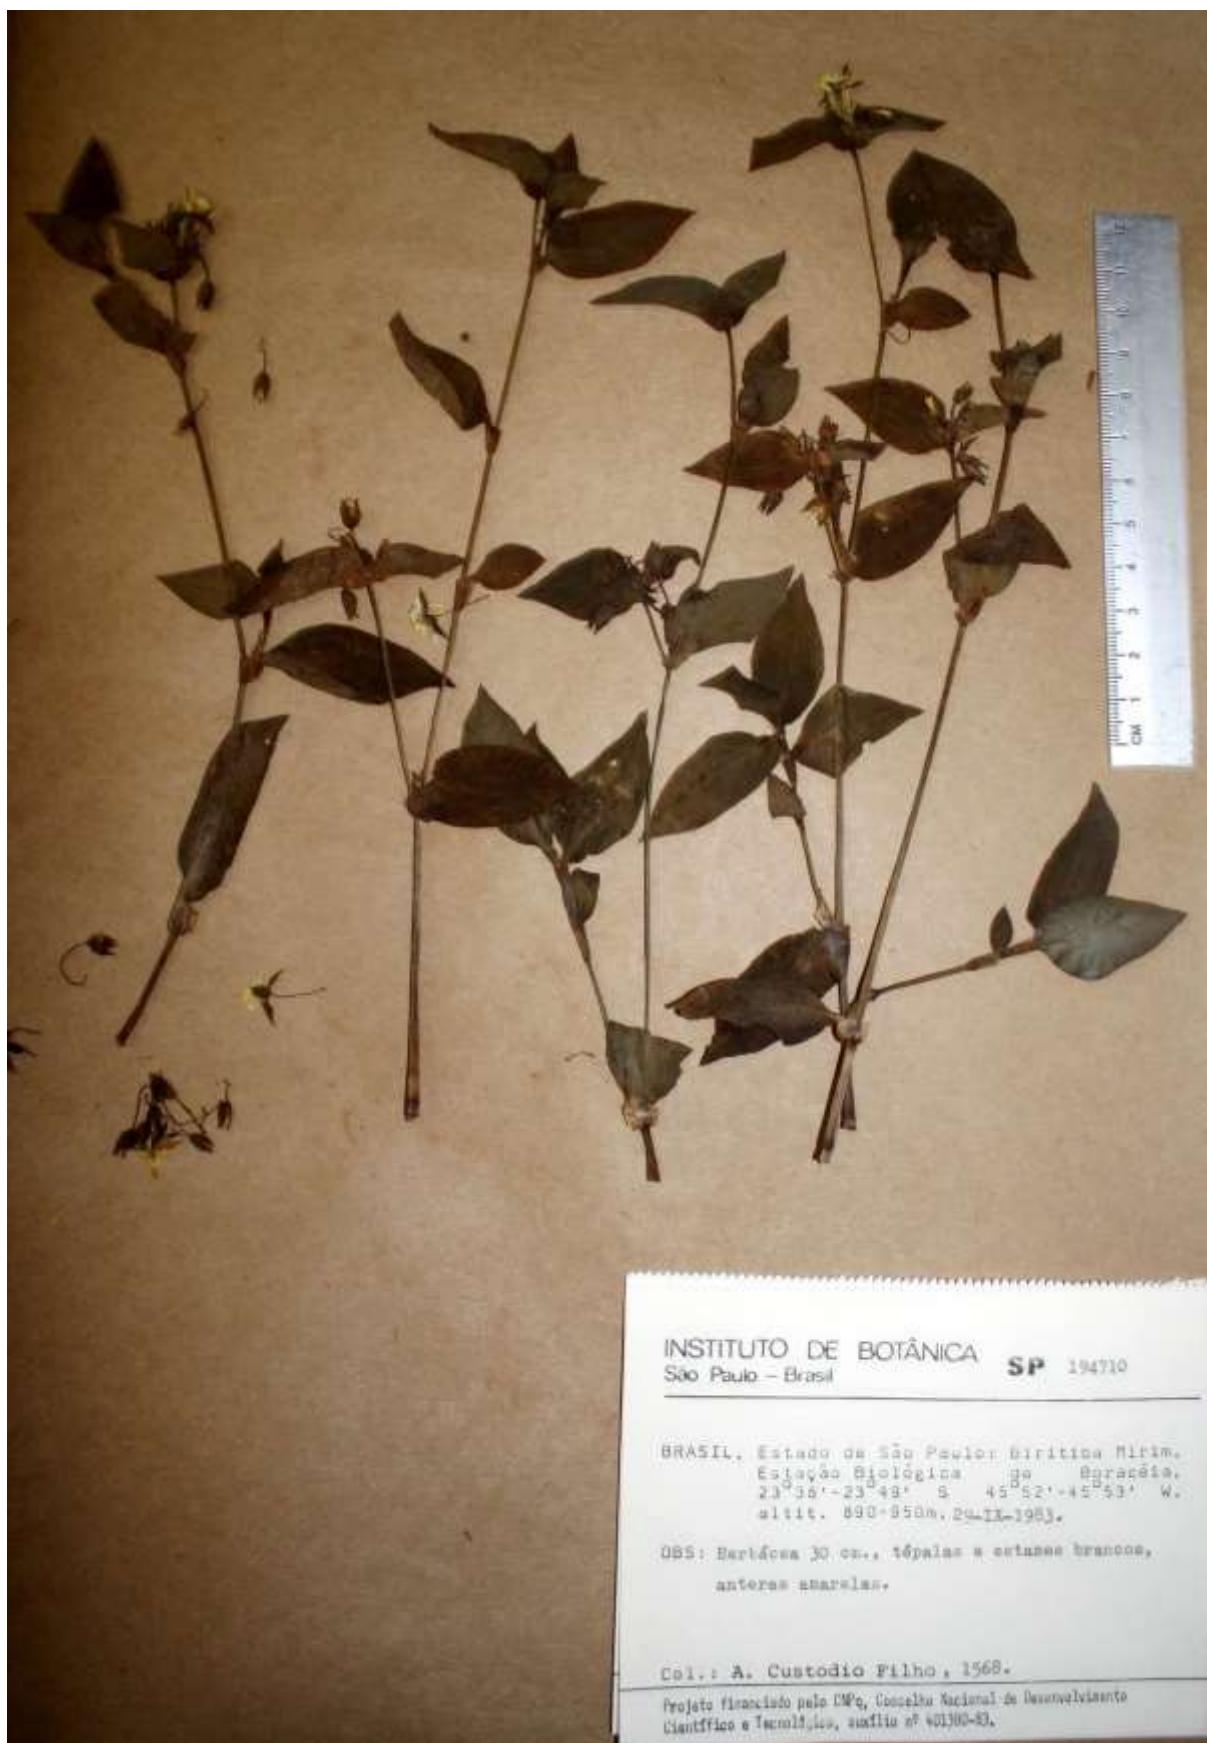

Fig. 9. *Tradescantia chrysophylla* M.Pell. Photo of the Isotype. Photo by M.O.O. Pellegrini.

Fig. 10. *Tradescantia cymbispatha* C.B.Clarke. **A**, habit, showing the opaque aspect of the leaves due to the velutine indumenta. **B**, detail of the stem, showing the predominant vinous color of the stem and leaves. **C**, detail of the leaf-sheaths and of the abaxial side of the blades, showing the velutine and hyaline indumenta. **D**, adaxial side of the leaf-blade, showing the inconspicuous secondary veins and the velutine and hyaline indumenta. **E**, detail of flower at post-anthesis, showing the pedicel's and sepals' velutine indumenta. **F**, flowers. Field photos by M.O.O. Pellegrini.

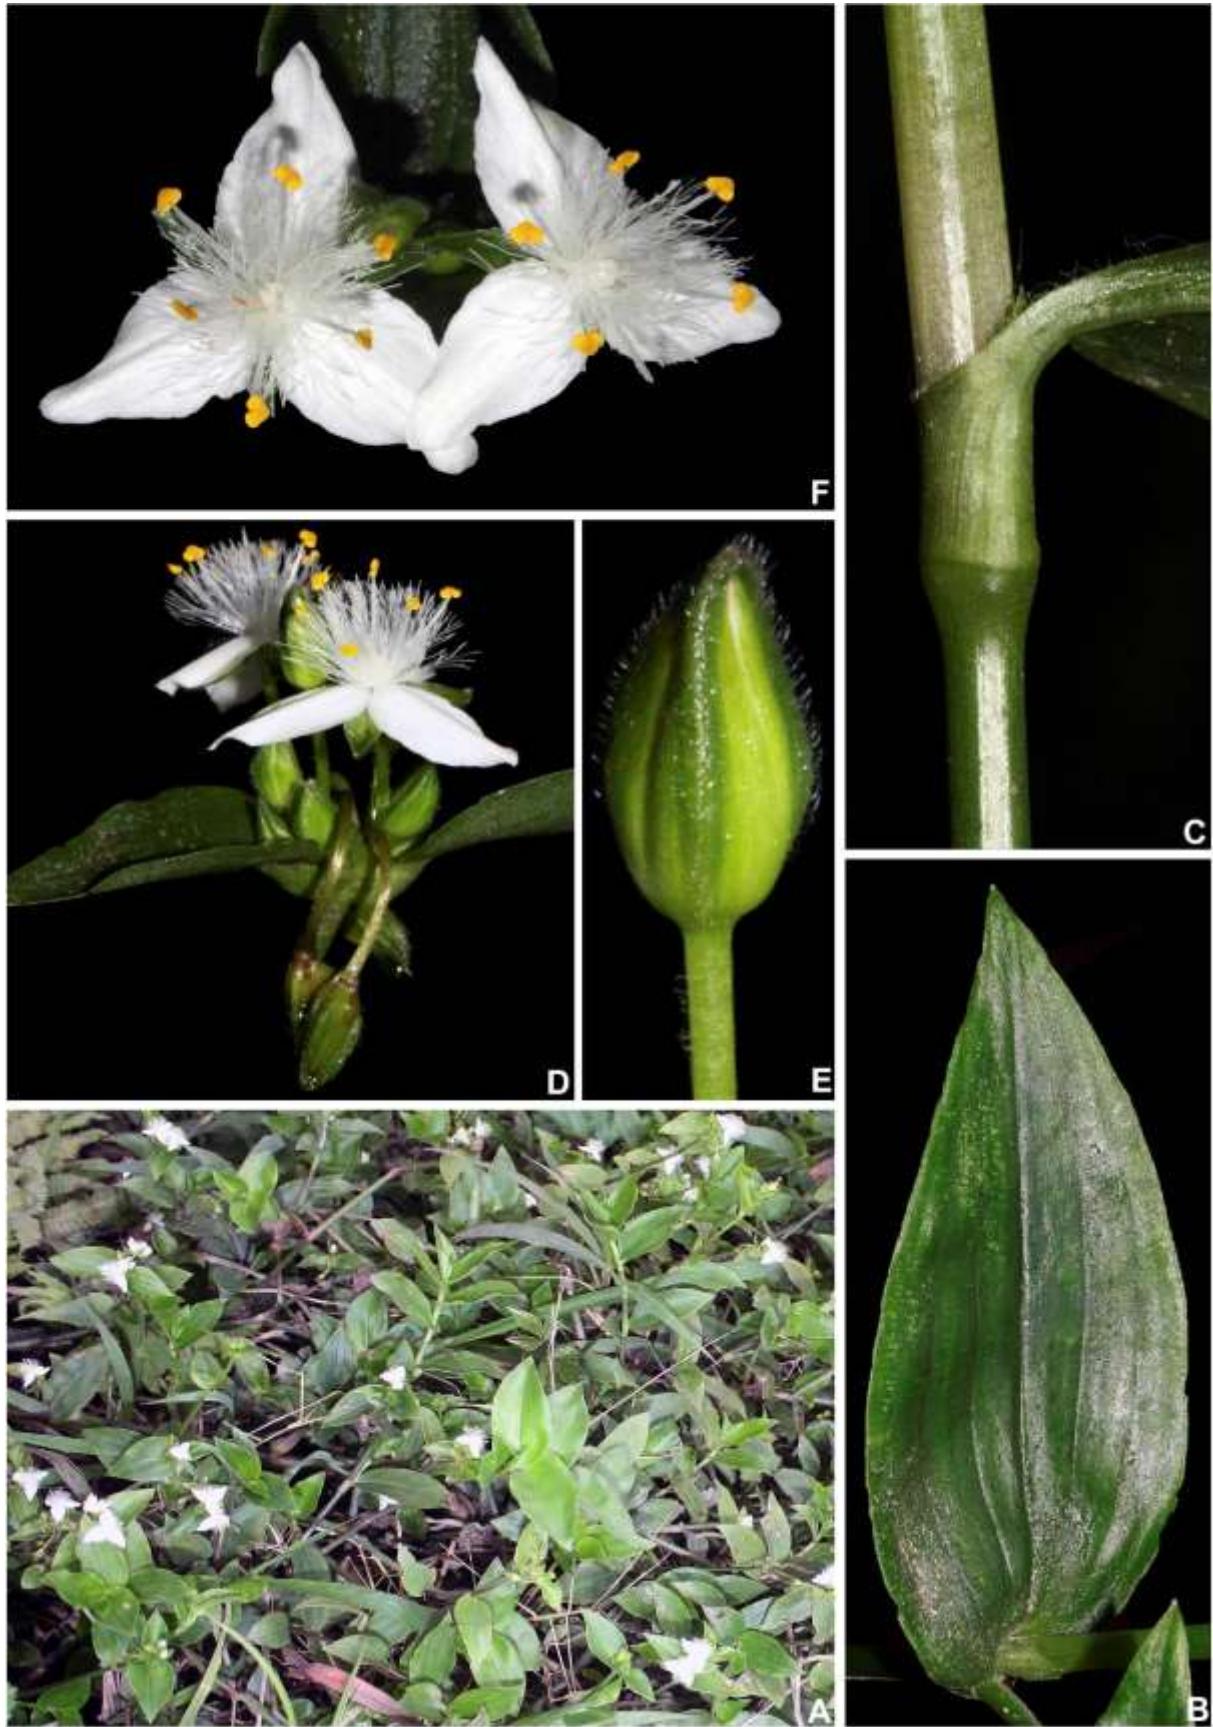

Fig. 11. *Tradescantia fluminensis* Vell. **A**, habit, showing the opaque aspect of the leaves due to the velutine indumenta. **B**, adaxial side of the leaf-blade, showing the impressed secondary veins. **C**, detail of the stem, showing the setose leaf-sheath margin. **D**, detail of the inflorescence, showing the saccate cincinni bract base, the plicate petals and the pistil the same length as the androecium. **E**, floral bud, showing the keeled sepals and the pilose indumenta restricted to them. **F**, flowers, showing the plicate petals. Field photos by M.O.O. Pellegrini.

Fig. 12. *Tradescantia mundula* Kunth. **A**, habit, showing the opaque aspect of the leaves due to the velutine indumenta. **B**, detail of the stem, showing the minutely velutine leaf-sheath and subtetiole. **C**, adaxial side of the leaf-blade, showing the vinous tinted coloration. **D**, adaxial side of the leaf-blade, showing the impressed secondary veins. **E**, flower. **F**, detail of the inflorescence, showing the saccate cincinni bract base. **G**, detail of flower at post-anthesis, showing the pedicel's and sepals' velutine indumenta. Field photos by M.O.O. Pellegrini.

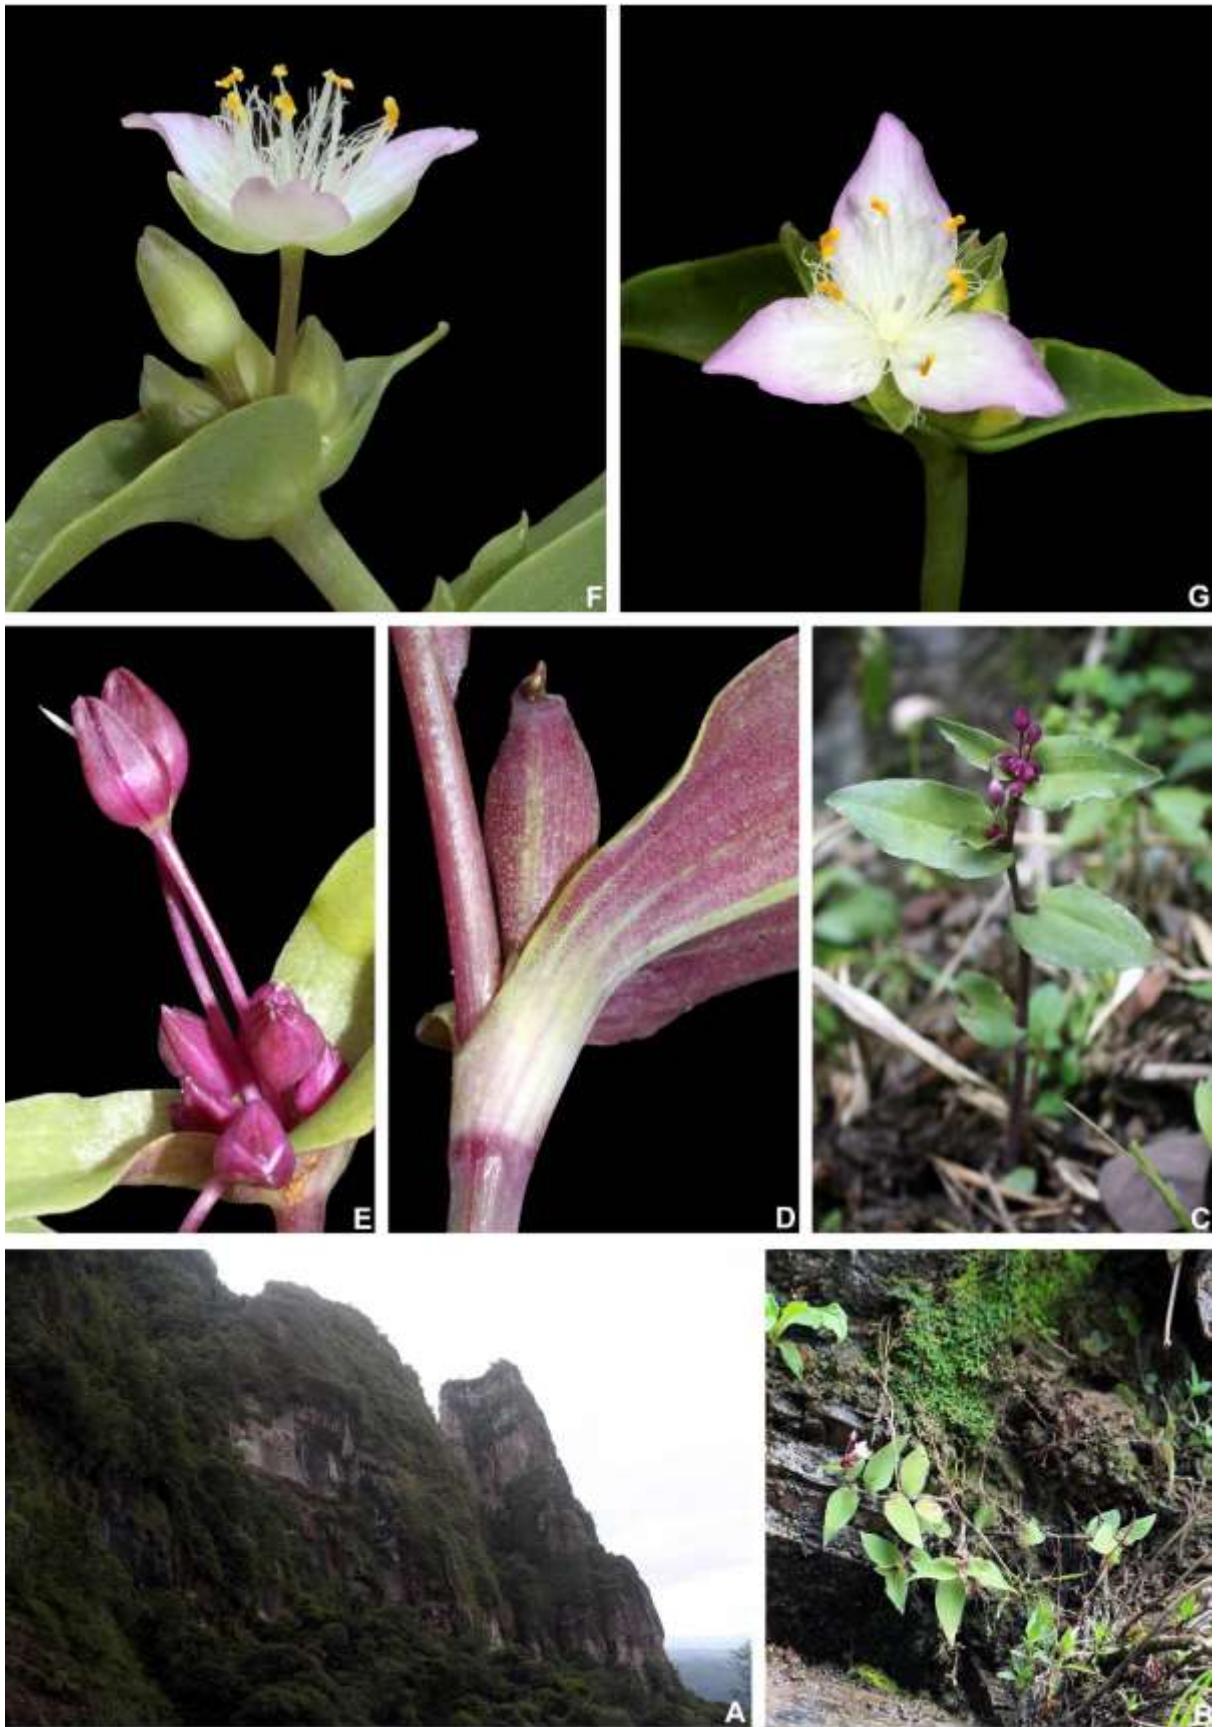

Fig. 13. *Tradescantia seubertiana* M.Pell. **A**, Serra do Corvo Branco, Santa Catarina, Brazil. **B**, habit, showing an individual growing on the wet rock wall. **C**, habit, showing the erect stem position. **D**, detail of the stem, leaf-sheath and the abaxial side of the leaf-blade, showing the reddish-purple coloration and the complete absence of indumenta. **E**, detail of the floral buds and flowers at post-anthesis, showing the reddish-purple coloration of the pedicels and sepals, and the complete absence of indumenta. **F**, detail of the inflorescence, showing the not saccate cincinni bract base, and side view of the flower, showing the pistil longer than the androecium. **G**, flower, showing the pink coloration of the petals. Field photos by M.O.O. Pellegrini.

Fig. 14. *Tradescantia tenella* Kunth. **A**, habit, showing fruticose growth-form. **B**, detail of the stem and the leaf-sheath, showing the leaf-opposed line of uniseriate hairs and the setose leaf-sheath margin. **C**, abaxial side of the leaf-blade, showing the subpetiole and the vinous coloration. **D**, adaxial side of the leaf-blade, showing the impressed secondary veins and the vinous stripe along the midvein. **E**, detail of the adaxial side of the leaf-blade, showing the hirsute indumenta. **F**, detail of the inflorescence, showing the saccate cincinni bract base. **G**, flower and flower at post-anthesis showing the glandulous indumenta of the sepals. Field photos by M.O.O. Pellegrini.

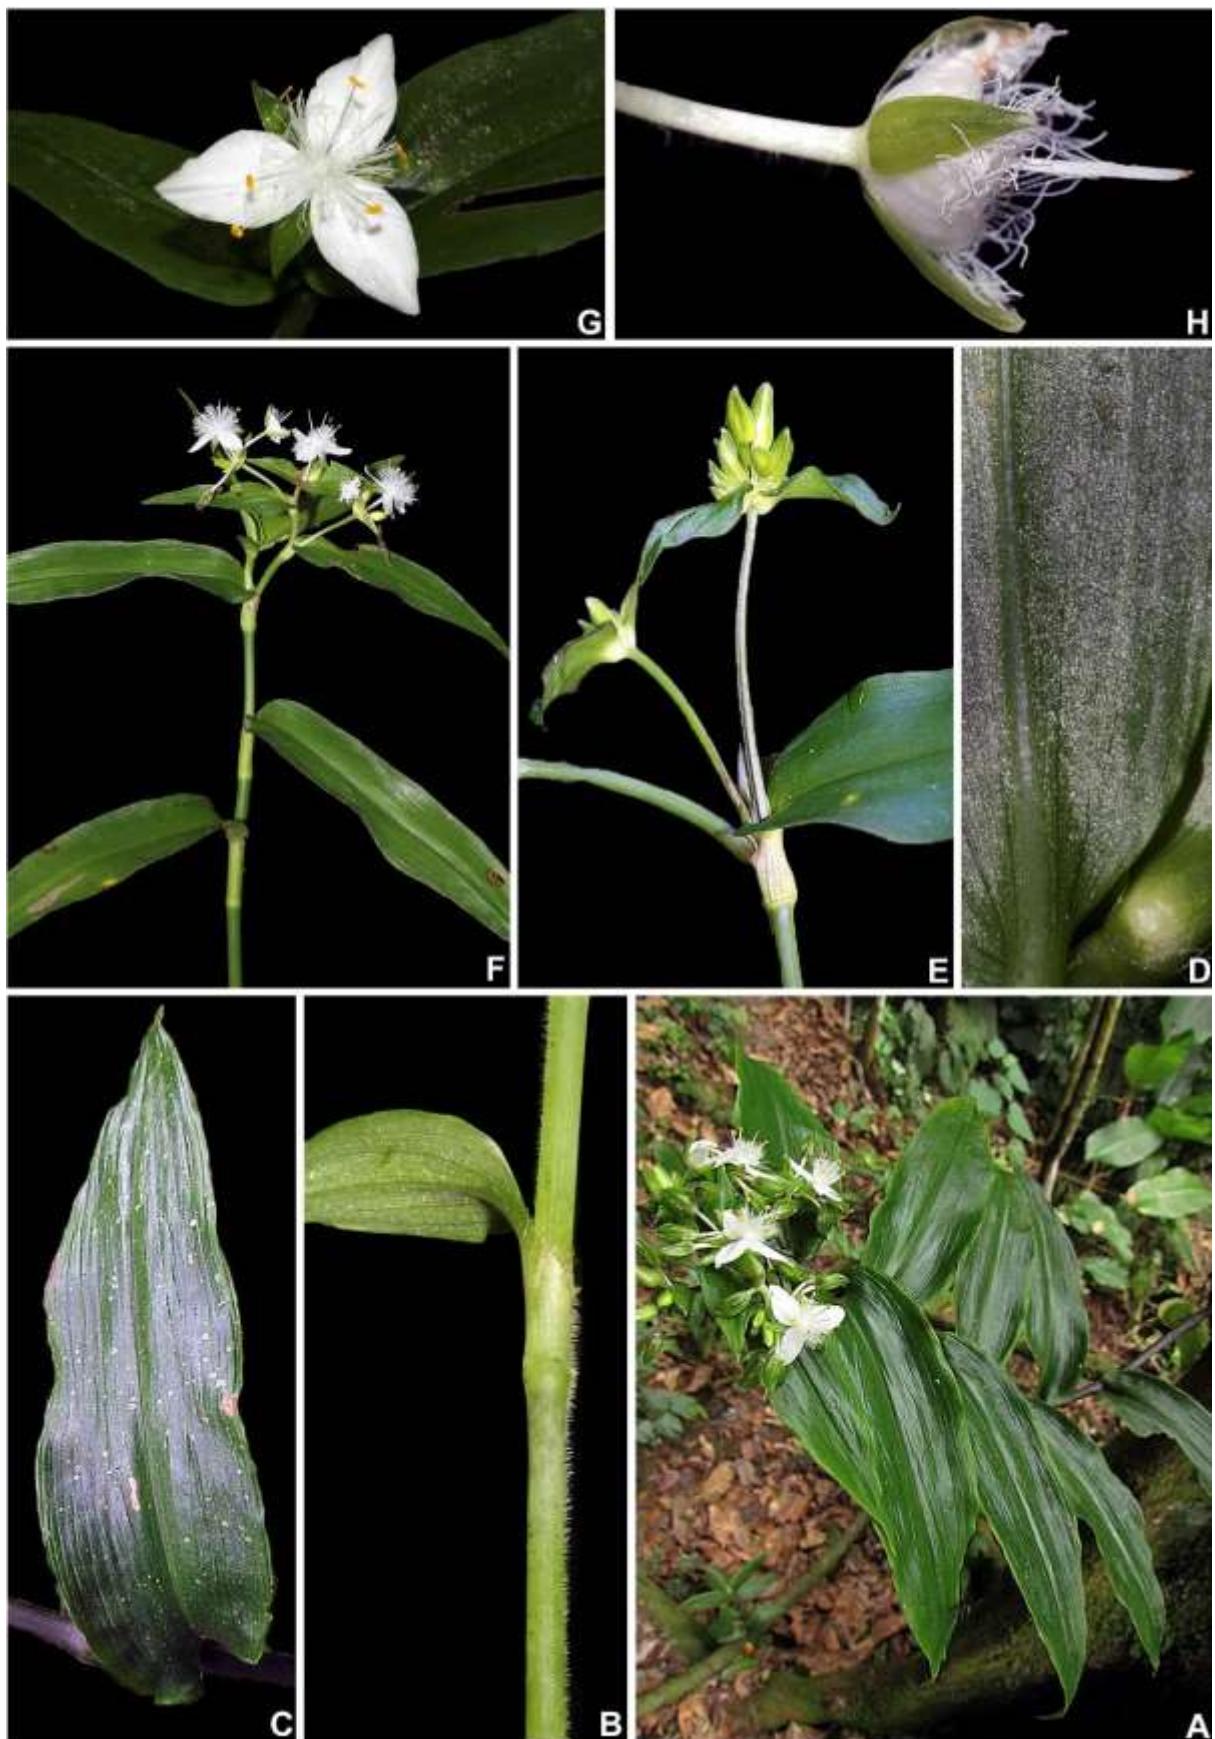

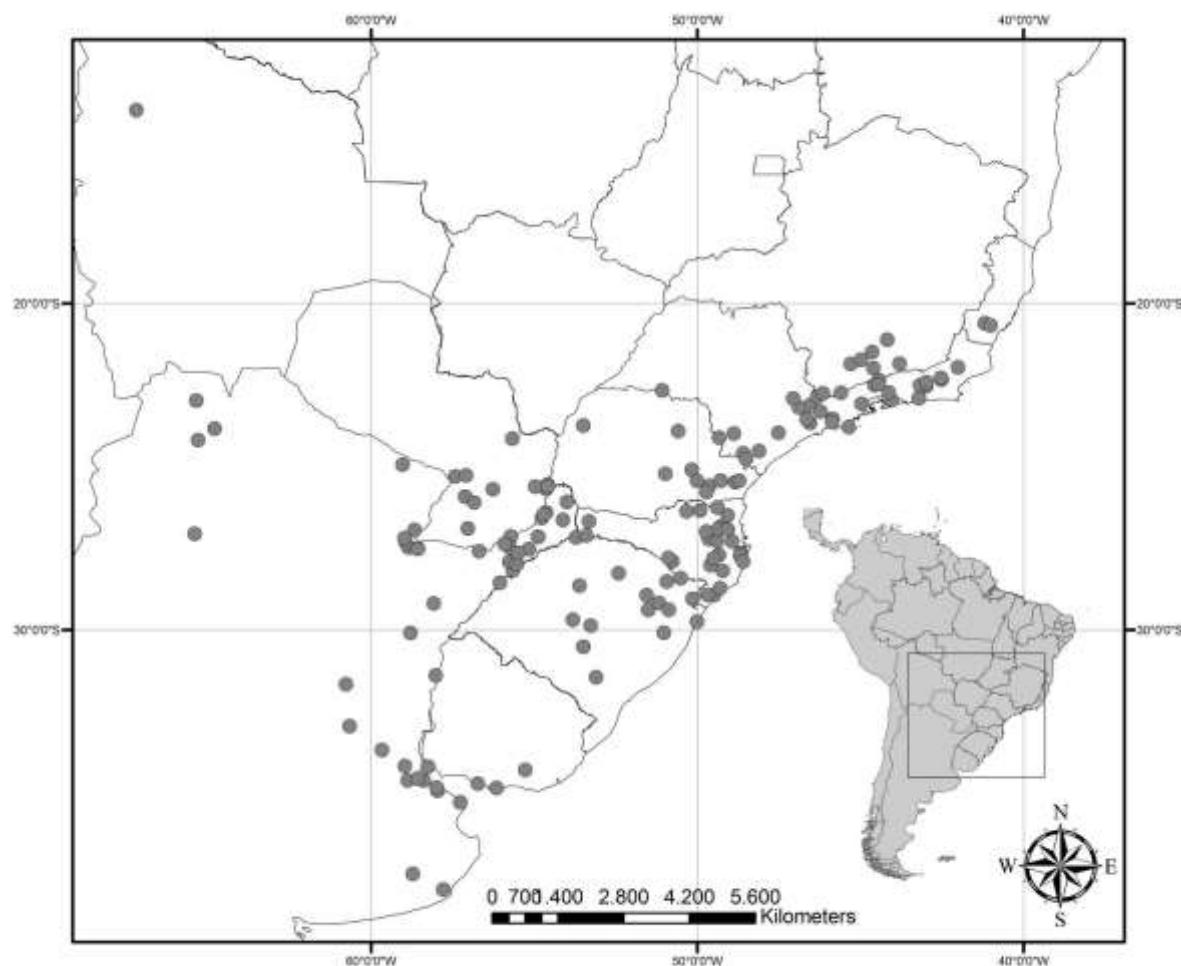

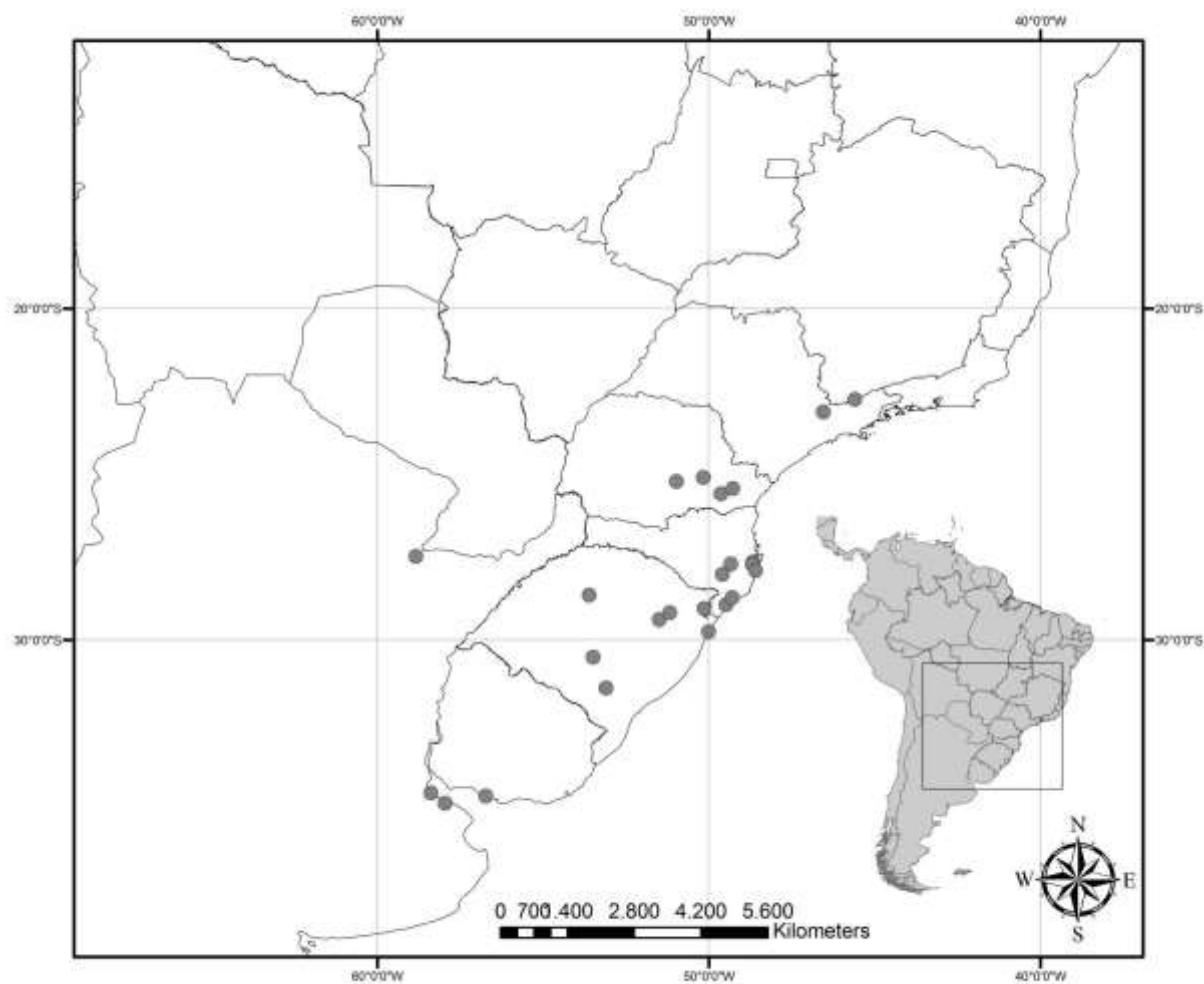

Fig. 15. *Tradescantia umbraculifera* Hand.-Mazz. **A**, habit, showing the species growing as an epiphyte. **B**, detail of the stem and the leaf-sheath, showing the leaf-opposed line of uniseriate hairs and the setose leaf-sheath margin. **C**, adaxial side of the leaf-blade, showing the impressed secondary veins. **D**, abaxial side of the leaf-blade. **E**, detail of two inflorescences emerging from the same leaf-sheath, showing the spathaceous cincinni bracts and their saccate base. **F**, general aspect of the stem showing the many and congested inflorescences at its apex. **G**, flower. **H**, flower at post-anthesis showing the white pedicel and the glabrous sepals. Field photos by M.O.O. Pellegrini, except A by L.A. Funez and F by H. Medeiros.

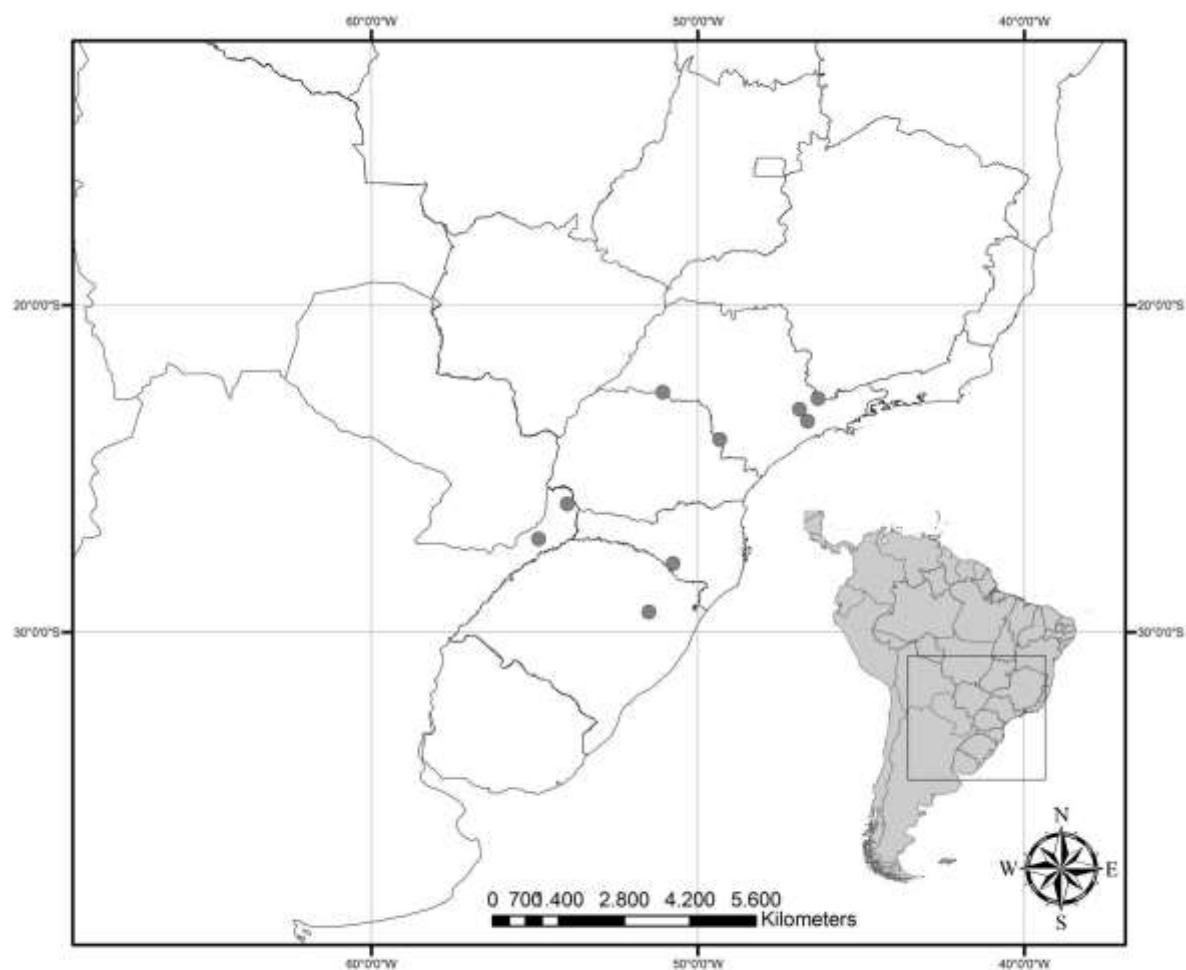

Fig. 16. *Tradescantia valida* G.Brückn. Photo of the Holotype. Photo by JSTOR.

SUPPLEMENT 1– LIST OF CHARACTERS

1. Roots, form: non-tuberous (0); tuberous (1)
2. Stem, posture: prostrate (0); ascending to erect (1)
3. Stem, consistency: herbaceous (0); fibrous to succulent (1)
4. Leaves, phyllotaxy: distichously-alternate (0); spirally-alternate to rosette arranged (1)
5. Leaves, position: evenly distributed along the stem (0); congested (1)
6. Leaves, insertion: sessile (0); subpetiolate (1)
7. Leaves, blade, shape: elliptic to lanceolate (0); linear (1); ovate (2); obovate to rotund (3)
8. Leaves, blade, architecture: flat (0); falcate to complicate (1)
9. Leaves, blade, indument, adaxial side: absent (0); present (1)
10. Leaves, blade, indument, adaxial side, type: velutine (0); pilose (1); hirsute (2) lanate (3); glandulous (4)
11. Leaves, blade, indument, adaxial side, color: hyaline (0); golden to light-brown (1)
12. Leaves, blade, indument, abaxial side: absent (0); present (1)
13. Leaves, blade, indument, abaxial side, type: velutine (0); pilose (1); hirsute (2) lanate (3); glandulous (4)
14. Leaves, blade, indument, abaxial side, color: hyaline (0); golden to light-brown (1)
15. Leaves, blade, base, shape: cuneate (0); truncate (1); obtuse to cordate (2)
16. Leaves, blade, base, symmetry: symmetrical (0); asymmetrical (1)
17. Leaves, blade, apex, shape: obtuse (0); acute (1); acuminate (2)
18. Leaves, blade, adaxial side, secondary veins, impression: conspicuous (0); inconspicuous (1)
19. Leaves, blade, adaxial side, longitudinal striations: absent (0); present (1)

20. Leaves, blade, abaxial side, color: green (0); vinous to brown (1)
21. Sinflorescence, structure: terminal or in the terminal portion of the stem (0); predominantly axillar to spike-like (1)
22. Inflorescence, structure: only with the main florescence (0); main florescence plus 1– many paraclades (1)
23. Inflorescence, emergency: not breaking through the leaf-sheath (0); breaking through the leaf-sheath (1)
24. Inflorescence, peduncle, development: sessile (0); pedunculated (1)
25. Inflorescence, peduncle, accessory bracts: absent (0); present (1)
26. Cincinni, number per main florescence: one (0); two (1); more than two (2)
27. Cincinni, disposition: subopposite (0); verticilate or back-to-back (1)
28. Cincinni, peduncle, development: sessile (0); pedunculated (1)
29. Cincinni, posture: non-geniculate (0); geniculate (1)
30. Cincinni, contraction: contracted (0); elongated (1)
31. Cincinni, fusion: free from one another (0); fused (1)
32. Cincinni, number per bract: one (0); more than one (1)
33. Cincinni, bracts supernumerary: absent (0); present (1)
34. Cincinni, bracts, development: vestigial (0); reduced (1); expanded (2)
35. Cincinni, bracts, shape: leaf-like (0); spathaceous (1)
36. Cincinni, bracts, fusion: free from one another (0); fused (1)
37. Cincinni, bracts, base: non-saccate (0); saccate (1)
38. Cincinni, bracts, base, overlapping: non-overlapping (0); overlapping (1)
39. Bracteoles, development: reduced (0); expanded but not enclosing the cincinnus (1) developed and enclosing the cincinnus (2).
40. Flower, shape: flat (0); tubular (1)

41. Flower, angle of display: 0° (0); torsion of 60° (1)
42. Flower, pedicel length: sessile to subsessile to about the same length of floral bud (0); long, longer than the length of floral bud (1)
43. Flower, pedicel, posture at anthesis and pre-anthesis: non-geniculate (0); geniculate (1)
44. Sepals, fusion: free (0); fused at least in some point (1)
45. Sepals, shape among each another: all equal or subequal (0); a single sepal differentiated (1)
46. Sepals, shape: elliptic (0); ovate (1); linear to lanceolate (2)
47. Sepals, keel: absent (0); present (1)
48. Sepals, consistency: membranous (0); chartaceous (1); fleshy (2)
49. Sepals, indumentum: glabrous (0); pilose to velutine to setose to lanate (1); hirsute (2); glandulous (3)
50. Sepals, color: hyaline to white (0); predominantly green (1); vinous to pink (2)
51. Petals, fusion: free (0); fused at least at some point (1)
52. Petals, shape: elliptic to ovate (0); obovate (1); lanceolate to linear (2); rhomboid to rotund (3)
53. Petals, claw: absent (0); present (1)
54. Petals, shape among each another: all equal to subequal (0); a single petal differentiated (1)
55. Petals, color: blue (0); white (1); pink to lilac to purple (2); green to hyaline (3)
56. Androecium, stamens, number (including staminodes): six (0); three to one (1)
57. Androecium, stamens, external series (opposite-sepal), bearding: absent to sparse and short (0); dense or sparse and long (1)
58. Androecium, stamens, external series (opposite-sepal), bearding, position: basal (0); up to median region (1); terminal (2)

59. Androecium, stamens, internal series (opposite-petal), bearding: absent to sparse and short (0); dense or sparse and long (1)
60. Androecium, stamens, internal series (opposite-petal), bearding, position: basal (0); up to the median region (1); terminal (2)
61. Androecium, stamens, series, relative size: equal (0); external series shorter (internal series longer) (1); two types of stamens in the same series, non-comparable series (2)
62. Androecium, stamens, filament, curvature: sigmoid (0); erect (1)
63. Androecium, stamens, fused to corolla: free (0); epipetalous (1)
64. Androecium, symmetry: actinomorphic (0); zygomorphic (1)
65. Androecium, stamens, external series (opposite-sepal), connective, general shape: non-expanded or elliptic (0); cordate to sagitate to transversally linear (1); quadrangular to curved (2); semicircular (3); rhomboid (4)
66. Androecium, stamens, internal series (opposite-petal), connective, general shape: non-expanded or elliptic (0); cordate to sagitate to transversally linear (1); quadrangular to curved (2); semicircular (3); rhomboid (4)
67. Androecium, stamens, external series (opposite-sepal), anther sac, shape: rounded (0); elliptic (1); reniform to curved (2); linear (3)
68. Androecium, stamens, internal series (opposite-petal), anther sac, shape: rounded (0); elliptic (1); reniform to curved (2); linear (3)
69. Androecium, stamens, pollen, color: white or similar colored to the corolla (0); yellow (1)
70. Androecium, stamens, pollen, ornamentation: spinous (0); reticulate (1); insular-cerebroid (2); areolate (3); granular-verrucous (4)
71. Gynoecium, pistil, relative length: shorter than stamens (0); equaling the stamens (1); longer than stamens (2)

72. Gynoecium, style, curvature: sigmoid (0); erect (1)
73. Gynoecium, stigma, shape: capitate to trilobate to subtrilobate (0); punctate (1); truncate to capitulate (2); peniciliform (3)
74. Seed, shape: elliptic to rectangular (0); triangular to triangular-rounded (1); tetrahedral (2)
75. Seed, embryotega, position: dorsal (0); lateral to semi-lateral (1)
76. Seed, testa, ornamentation: smooth (0); reticulate to foveolate (1); striate to costate to tuberculate (2); rugose (3)
77. Seed, hilum: punctate to elliptic (0); linear (1); curved (2)
78. Anatomy, leaf epidermis, silica crystals in specialized cells: absent (0); in differentiated cells with thickened walls (1); in non-differentiated cells with thin walls (2)
79. Anatomy, mesophyll, bundle sheath: diffuse (0); with sclerenchymatic extensions (1)
80. Chromosomes, number: $n= 4-5$ or multiple of (0); $n= 6$ or multiple of (1); $n= 7-8$ or multiple or varying from 5–6–10–11 due to Robertsonian Change (2); $n= 8$ or multiple of (3); $n= 17$ or multiple of (4); $n=$ probable multiple of 10 (5)
81. Chromosomes, size: small, equal or smaller than $5\mu\text{m}$ (0); medium, larger than $5\mu\text{m}$ and smaller than $10\mu\text{m}$ (1); large, equal or larger than $10\mu\text{m}$ (2)
82. Chromosomes, karyotype, homogeneity: unimodal (0); bimodal (1)
83. Phytochemical, hidroxiluteolin: absent (0); present (1)
84. Phytochemical, C-glycosides: absent (0); mono-C-glycosides (1); di-C-glycosides (2)
85. Phytochemical, flavonoid, quercetin: absent (0); present (1)
86. Phytochemical, sulfated phenolic acid: absent (0); present (1)

SUPPLEMENT 2– MORPHOLOGICAL MATRIX

Matrix with the 49 terminals and the first 30 characters. The characters that were not coded due to lack of data of the analyzed specimens and/or from literature sources are coded as “?”; characters that did not apply were coded as “-”; and the polymorphic characters were coded with a “/” between each state it presented.

CONSIDERAÇÕES FINAIS

A revisão nomenclatural realizada para os nomes brasileiros de *Tradescantia* resultou no reestabelecimento de dois nomes (*T. cymbispatha* e *T. mundula*) previamente tratados na sinonímia de *T. fluminensis*, na descrição de uma nova espécie da Bolívia e a elucidação da posição de *T. cymbispatha* como membro de *T.* seção *Austrotradescantia*. Mais especificamente, durante a análise dos nomes de *Tradescantia* publicados na *Flora fluminensis*, foram designados cinco lectótipos, um epítipo e um novo sinônimo. Ainda, na tentativa de elucidar a identidade e a aplicação do nome *T. cymbispatha* foram designados dois novos sinônimos, dois lectótipos e foram apresentados caracteres morfológicos para a diferenciação entre *Tradescantia* seções *Austrotradescantia* e *Cymbispatha*. Com isso, também se confirmou a ausência de representantes de *T.* seção *Cymbispatha* em território brasileiro. Apesar da extensa revisão nomenclatural feita no presente trabalho, *Tradescantia* ainda apresenta nomes de aplicação incerta que necessitam ser melhor analisados.

Para desenvolvimento da filogenia morfológica foram levantados 86 caracteres morfológicos, focando principalmente na macromorfologia das plantas estudadas. Destes, 82 se mostraram informativos para parcimônia. Entretanto, caracteres micromorfológicos, citológicos e fitoquímicos, levantados por meio de literatura, se mostraram bastante importante para a resolução e sustentação de vários clados dentro de *Tradescantia*. Dessa maneira, é bastante possível que trabalhos focados na anatomia do grupo virão a contribuir grandemente para o melhor entendimento de suas relações filogenéticas. *Tradescantia* não foi recuperado como monofilético e nossos resultados evidenciam a necessidade de transferir *T. guatemalensis* para o gênero *Elasis*. Dessa maneira, *Tradescantia* s.s. apresenta como sinapomorfias caule ereto, brácteas do cíncino expandidas, sementes elipsoides a retangulares com hilo linear e epiderme foliar sem cristais de sílica em células especializadas. Os resultados obtidos com base na análise de caracteres morfológico é altamente congruente com os resultados recuperados com base em caracteres moleculares. *Tradescantia* encontra-se dividido em três grandes clados, sendo *T.* seção *Austrotradescantia* o primeiro grupo a divergir, seguido pelo clado *Cymbispatha* (composto pelas seções *Campelia*, *Corinna*, *Cymbispatha* e *Zebrina*), e posteriormente por *Core Tradescantia* (composto pelas seções *Mandonia*, *Parasetcreasea*, *Separothecea*, *Setcreasea* e *Tradescantia*). *Core Tradescantia* apresenta

a maior diversidade de espécies do gênero, e apresenta distribuição relacionada às Florestas Tropicais Sazonais Secas e regiões desérticas norte-americanas. Esses resultados nos permitem, em um futuro próximo, expandir a matriz morfológica para incluir mais representantes de *Core Tradescantia*, e realizar uma análise combinada com os dados moleculares já existentes.

O tratamento taxonômico realizado para *Tradescantia* seção *Austrotradescantia* resultou no reconhecimento de 10 espécies, sendo duas espécies previamente consideradas *insertae sedis*, dois nomes reestabelecidos, duas espécies novas para a ciência e quatro lectótipos. A seção apresenta distribuição exclusivamente sul-americana, extratropical austral, tendo como centro de diversidade a região Sul do Brasil. Nessa região são registradas nove das 10 espécies aceitas para o grupo. As espécies de *T.* seção *Austrotradescantia* ocorrem no Chaco, Floresta Atlântica e Pampa, tendo preferência por ambientes antropizados, formações campestres, vegetações sobre afloramentos rochosos, sub-bosques de florestas ombrófilas densas e florestas estacionais semidecíduas, e mais raramente ocorrendo em formações de restinga. A distribuição de praticamente todos os táxons foi ampliada devido ao esforço de coleta por toda a distribuição brasileira da seção, somado a grande quantidade de coleções analisadas. A exceção é *T. fluminensis*, que teve a sua circunscrição revista, gerando uma diminuição na distribuição tradicionalmente aceita para a espécie. As duas novas espécies descritas são os únicos táxons endêmicos do território brasileiro, enquanto *T. valida* é endêmica da Bolívia. O presente trabalho conta com uma chave inédita para *T.* seção *Austrotradescantia*, possibilitando uma identificação precisa das espécies.

COMMELINACEAE

Lidyanne Yuriko Saleme Aona-Pinheiro, Marco Octávio Pellegrini,
 Arthur Sérgio Mouço Valente, Daniel Maurenza, Danielli Cristina Kutschenco,
 Júlio Souza Reis Júnior, Marcelo Bueno de Abreu

Commelinaceae compreende 42 gêneros e cerca de 664 espécies (Faden, 1998; Hardy; Faden, 2004; Aona *et al.*, 2012; Aona-Pinheiro; Amaral, 2012). Podem ser reconhecidos alguns centros de diversidade para a família como: Brasil (*Dichorisandra* J.C. Mikan), México (*Gibasis* Raf.), África (*Aneilema* R.Br.) e Ásia (*Commelina* L.) (Aona, 2008; Hunt, 1986; Faden, 1991; Gajurel; Shrestham, 2009, respectivamente). No Brasil, ocorrem 13 gêneros e cerca de 69 espécies, podendo ser encontradas de norte a sul em formações florestais e camprestes, em áreas alagadas, alteradas, sendo também amplamente cultivadas como ornamentais (Barreto, 1997; Aona; Pellegrini, 2012). Apesar disso, poucas espécies brasileiras estão presentes em Campos de Altitude e outros locais acima da faixa de 1.500 m.s.m. São plantas geralmente suculentas, eretas ou decumbentes, raramente escandentes, em geral terrestres, às vezes rupícolas, saxícolas e aquáticas emergentes, com apenas dois gêneros exclusivamente epífitos: *Belosynapsis* Hassk. e *Cochliostema* Lem. (Faden, 1985). Apresentam folhas simples, alternas, dísticas ou espiraladas; bainha fechada. Inflorescência terminal e/ou axilar ou basal, composta por cincinatos agregados em tirso, subtendidas por brácteas foliáceas ou envolvidas por brácteas espatáceas. Suas flores trímeras são em geral deliquescentes e tornam Commelinaceae uma das famílias mais difíceis de serem estudadas com base em material herborizado (Faden, 1991). Apresentam grande variação no androceu, tendo como base 6 estames perfeitos, em 2 séries, mas 1–4 destes podem estar modificados em estaminódios ou suprimidos em alguns gêneros. Suas anteras apresentam deiscência rimosa ou, mais raramente, poricida. No Brasil, Commelinaceae inclui diversas espécies, ocorrendo na Amazônia, na Caatinga e no Cerrado, mas tendo sua maior diversidade na Mata Atlântica, em especial nos Estados da Bahia, Espírito Santo e Rio de Janeiro (Aona; Pellegrini, 2012). Há um grau acentuado de endemismo e especialização nas linhagens na tribo Dichorisandrinae, à qual pertencem os gêneros *Dichorisandra* e *Siderasis* Raf. As plantas desses gêneros têm grande valor ornamental, ocorrendo principalmente em matas úmidas bem preservadas (Aona, 2008), e sendo ameaçadas principalmente pela perda de qualidade de habitat e por coletas ilegais. Além disso, a Mata Atlântica tem apenas 11,37% de sua cobertura original (Ribeiro *et al.*, 2009) e é considerada um dos hotspots mundiais, onde um número expressivo de espécies recém-descritas ou ainda desconhecidas para a ciência pode estar em sério risco de extinção.

Dichorisandra acaulis Cogn.

Risco de extinção: EN B1ab(i,ii,v) ⓘ

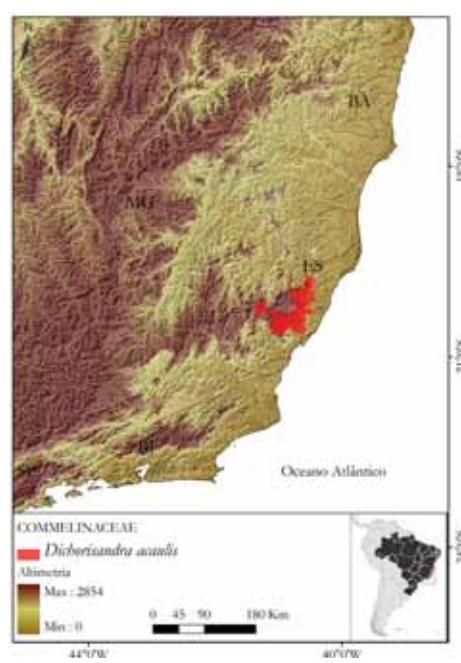

Avaliador: Daniel Maurenza

Data: 11-09-2012

Distribuição: ES

Bioma: Mata Atlântica

Justificativa: *Dichorisandra acaulis* é uma erva com distribuição restrita ao Estado do Espírito Santo. A EOO estimada é inferior a 5.000 km², colocando a espécie na categoria “Em perigo” (EN). As Matas de Tabuleiros foram historicamente desmatadas devido à expansão da ocupação urbana e à mudança do uso do solo destinado à agricultura, o que reduziu a EOO da espécie. Assim, supõe-se que as ameaças tornaram a população severamente fragmentada, com as subpopulações isoladas em áreas legalmente protegidas. Devido ao seu potencial ornamental, a AOO e o número de indivíduos adultos também podem estar em declínio.

Dichorisandra glaziovii Taub.

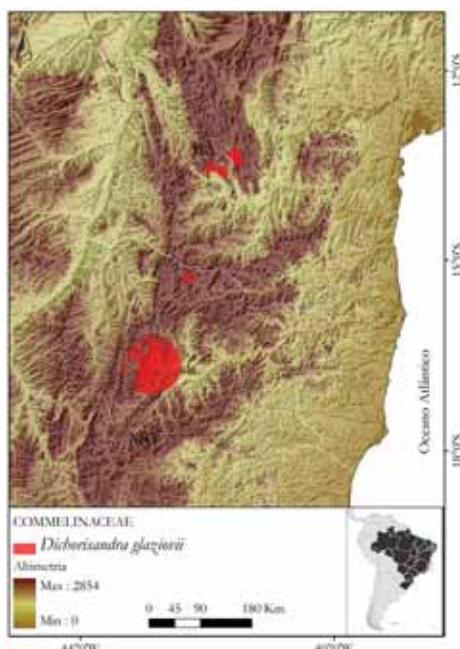

Risco de extinção: VU D2 🌎

Avaliador: Daniel Maurenza

Data: 11-09-2012

Distribuição: BA; MG

Biomas: Caatinga, Cerrado, Mata Atlântica

Justificativa: *Dichorisandra glaziovii* é uma espécie herbácea com distribuição restrita aos campos rupestres da Serra do Espinhaço (MG) e da região da Chapada da Diamantina (BA), locais ameaçados por perda de habitat. As subpopulações conhecidas no município Grão Mogol sofrem pressão principalmente pela atividade mineradora, que causa declínio de localidade. Já as subpopulações da Chapada da Diamantina estão em risco por diversos fatores, tais como a atividade agropecuária, o fogo, o turismo e a invasão de espécies exóticas. Similarmente, o município de Salinas apresenta desmatamento devido à atividade agropecuária que é a base econômica da região. Assim, são identificadas três situações de ameaça que podem tornar a espécie criticamente em perigo de extinção ou extinta em futuro próximo.

Dichorisandra leucophthalmos Hook.

Risco de extinção: VU A4c;B1ab(iii,v) 🌎

Avaliador: Daniel Maurenza

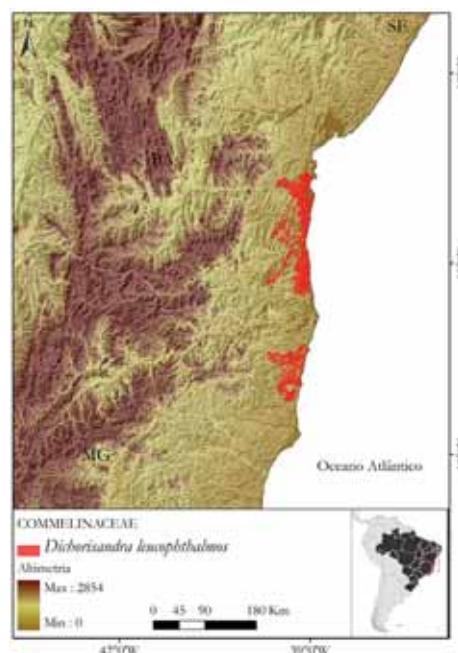

Data: 11-09-2012

Distribuição: BA

Bioma: Mata Atlântica

Justificativa: *Dichorisandra leucophthalmos* é uma espécie herbácea terrícola que ocupa o sub-bosque das florestas úmidas do sul da Bahia. Na área de ocorrência, é comum o uso do sistema agrícola de cabruca, que elimina

a vegetação de sub-bosque para o plantio do cacau, um método que atinge exatamente o extrato ocupado pela espécie. O uso do sistema de cultivo cabruca diminuiu nos últimos anos, ao passo que a atividade pecuária aumentou, e há perspectiva de crescimento, tendo em vista as boas condições ambientais para essa prática. Foi estimada uma EOO inferior a 20.000 km², colocando a espécie na categoria “Vulnerável” (VU). As subpopulações conhecidas indicam menos de 10 situações de ameaças, que, pelo exposto acima, reduzem a EOO, AOO, qualidade do habitat e o número de indivíduos maduros. Ademais, as ameaças tornam possível inferir que houve uma redução populacional no passado e projetar uma diminuição da população num futuro imediato. Considerando que a espécie é uma erva de sub-bosque e rizomatosa, suspeita-se que apresente crescimento lento e tempo de geração de cerca de cinco anos, de modo que as ameaças podem reduzir o tamanho populacional em pelo menos 30% no período de três gerações.

Dichorisandra neglecta Brade

Risco de extinção: CR★B2ab(iii,v) 🌎

Avaliador: Daniel Maurenza

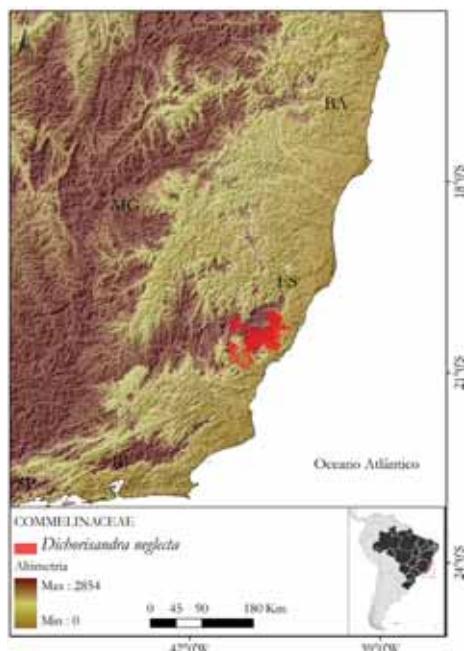

Data: 11-09-2012

Distribuição: ES

Bioma: Mata Atlântica

Justificativa: *Dichorisandra neglecta* é uma espécie herbácea rara e restrita ao Estado do Espírito Santo. A única coleta botânica conhecida é o material-tipo, um indivíduo de 1 m de altura, localizado em mata úmida dentro de uma fazenda particular. Assim, a AOO estimada é inferior a 10 km², colocando a espécie na categoria “Criticamente em perigo” (CR). O município de ocorrência, em 2010, contabiliza apenas 10,8% dos remanescentes de Mata

Atlântica, um resultado proveniente dos diversos ciclos econômicos de monoculturas como a cana-de-açúcar, mandioca, banana e café, que desmataram as áreas florestais. O crescimento populacional também é responsável pela perda de biodiversidade, uma vez que o senso demográfico apontava aproximadamente 143.000 habitantes em 1991, e 195.000 em 2007. Foi localizada apenas uma subpopulação, que, em vista do que foi exposto, submete a população de *D. neglecta* ao declínio da EOO, AOO, da qualidade do habitat e do número de indivíduos adultos. Ademais, considerando que o material-tipo foi coletado em 1949, é possível suspeitar que a espécie esteja extinta.

Siderasis fuscata (Lodd.) H.E.Moore

Risco de extinção: EN B1ab(ii,iii,v)+2ab(ii,iii,v)

Avaliador: Daniel Maurenza

Data: 11-09-2012

Distribuição: RJ

Bioma: Mata Atlântica

Justificativa: *Siderasis fuscata* é uma espécie herbácea endêmica do Brasil. Ocorre nos sub-bosques das florestas litorâneas do Estado do Rio de Janeiro, na faixa altitudinal sub-montana, indicando alta especificidade de habitat. A EOO estimada é inferior a 5.000 km² e a AOO é menor que 500 km², colocando a espécie na categoria “Em perigo” (EN). As subpopulações conhecidas estão localizadas em florestas de região metropolitana, nos municípios do Rio de Janeiro e Niterói, que tiveram 82,4% e 77,3% de área desmatada, limitando a população a localidades severamente fragmentadas. Embora as localidades conhecidas estejam inseridas em áreas de proteção integral, o fácil acesso humano e outros fatores advindos da expansão urbana são ameaças que resultam no declínio da qualidade

do habitat da espécie. O potencial ornamental de *S. fuscata* torna o extrativismo uma ameaça que causa o declínio da AOO e do número de indivíduos maduros. Ademais, o registro botânico mais recente foi coletado em 1982, de modo que se fazem necessárias maiores investigações sobre a atual distribuição da espécie.

COMMELINACEAE

Marco Octávio de Oliveira Pellegrini, Lidyanne Yuriko Saleme Aona-Pinheiro,
Luiz Santos Filho, Thiago Serrano

Commelinaceae caracteriza-se por ervas ou lianas, terrícolas, rupícolas ou palustres, raramente epífitas, distribuídas em 41 gêneros e aproximadamente 670 espécies. A família ocorre principalmente nas regiões tropicais e subtropicais em formações florestais e campestres (Faden & Hunt, 1991). No Brasil, é representada por 14 gêneros e cerca de 80 espécies. Desses, 10 gêneros e 29 espécies são encontradas no Cerrado (Aona & Pellegrini, 2014). Diferentemente da Floresta Atlântica que é o centro de diversidade de *Dichorisandra* (Aona, 2008), o Cerrado é fortemente representado pela tribo Commelineae e pela subtribo Tradescantiinae, em especial pelos gêneros *Commelina* e *Tripogandra* (Aona & Pellegrini, 2014). *Tripogandra* é proporcionalmente um dos gêneros mais problemáticos no Brasil, com três das sete espécies listadas para o país sendo pouco conhecidas e raramente coletadas (Pellegrini *et al.*, 2013). Desses sete espécies, duas foram consideradas como raras (Barreto, 2009) e categorizadas como ameaçadas, segundo os critérios IUCN. Inúmeras espécies de Commelinaceae de áreas secas apresentam vários níveis de suculência em seus caules e folhas, que aliados as suas belas flores, as tornam de grande interesse ornamental e horticultural. Dos grupos brasileiros de áreas secas, *Tripogandra* e *Tradescantia*, seção Austrotradescantia, são especialmente cobiçados por colecionadores de todo mundo (Hunt, 2001). Essas plantas são fortemente ameaçadas pela coleta seletiva de indivíduos como ornamentais (Hunt, 1979), a mineração de calcário, a intensa exploração agropecuária e o crescimento urbano (Herrmann *et al.*, 1998; Pellegrini *et al.*, 2013).

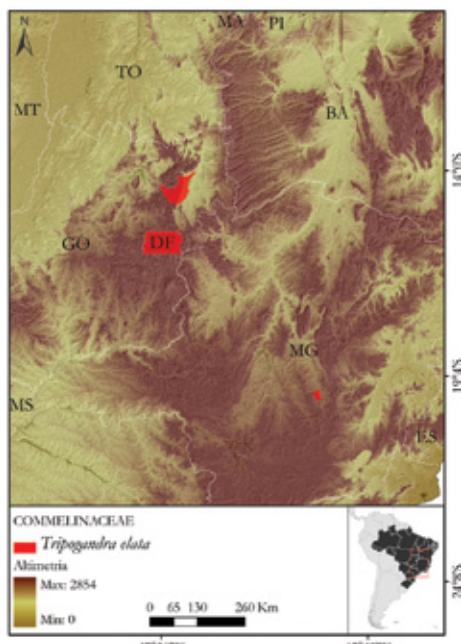

Tripogandra elata D.R.Hunt

Risco de extinção: EN B2ab(i,ii,iii,iv,v)

Avaliador(a): Luiz Santos Filho

Data: 06-02-2014

Bioma: Cerrado

Justificativa: Espécie herbácea de ocorrência no Distrito Federal e nos estados de Goiás e Minas Gerais (AOO = 24 km²) (Hunt, 1979; Barreto, 2009; Aona & Pellegrini, 2013). Desenvolve-se em Cerrado *lato sensu*, sendo encontrada em Matas de Galeria sobre rochas calcárias,

onde forma pequenas subpopulações (Hunt, 1979; Barreto, 2009; Aona & Pellegrini, 2013). Apesar de protegida pela APA Carste de Lagoa Santa (CNCFlora, 2013) e cultivada no Museu de Biologia Mello Leitão (MBML) e no Jardim Botânico de Belo Horizonte (Pellegrini, com. pess.), suas subpopulações são diretamente afetadas pela coleta seletiva de indivíduos férteis para ornamentação (Hunt, 1979) e pela mineração de calcário desenvolvida na área de distribuição da espécie (Pellegrini, com. pess.), o que a torna suscetível à extinção caso não sejam tomadas medidas de controle das ameaças incidentes.

Tripogandra warmingiana (Seub.) Handlos

Risco de extinção: VU A4c;B2ab(i,ii,iii,iv)

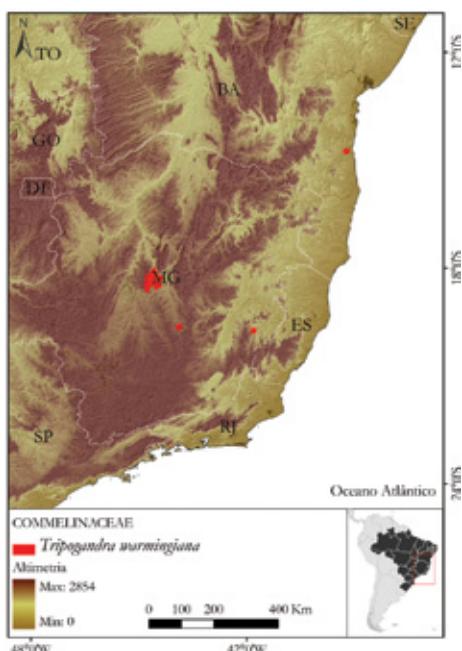

Avaliador(a): Luiz Santos Filho

Data: 07-02-2014

Bioma: Cerrado; Mata Atlântica

Justificativa: Espécie herbácea, popularmente conhecida como “marianinha”, ocorre nos estados da Bahia, Espírito Santo, Minas Gerais e Rio de Janeiro (Aona & Pellegrini; Pellegrini *et al.*, 2013). É encontrada em Cerrado e Mata Atlântica, onde se desenvolve em Floresta de Galeria sobre afloramentos calcários, Floresta Semidecidual e Floresta Higrófila (Pellegrini *et al.*, 2013). Forma subpopulações constituídas por poucos indivíduos, preferencialmente em locais sombreados e úmidos (Pellegrini *et al.*, 2013). Está sujeita a menos de 10 situações

de ameaça, considerando suas localidades de ocorrência, sendo poucas as subpopulações protegidas por unidades de conservação. Esse fato, somado à intensa exploração do solo com as atividades agropecuárias (Herrmann *et al.*, 1998; Pellegrini *et al.*, 2013), a mineração e o desenvolvimento urbano (Herrmann *et al.*, 1998), afeta sua área de distribuição e a coloca em risco de extinção. A espécie pode apresentar uma redução populacional significativa em um futuro próximo, causada pelas ameaças incidentes que acarretam declínio de EOO, AOO, da extensão e qualidade de seus habitats e da representatividade de suas subpopulações.

BASELLACEAE

Marco Octávio de Oliveira Pellegrini^{1,2} e Cassia Mônica Sakuragui³

1. Universidade Federal do Rio de Janeiro, CCS, Instituto de Biologia, Programa de Pós-Graduação em Biodiversidade e Biologia Evolutiva.
2. Instituto de Pesquisas Jardim Botânico do Rio de Janeiro, Rua Pacheco Leão 915, 22460-030, Jardim Botânico, Rio de Janeiro, RJ, Brasil.
3. Universidade Federal do Rio de Janeiro, CCS, Instituto de Biologia, Departamento de Botânica, Av. Carlos Chagas Filho, 373 - Sala A1-088 - Bloco A, Ilha do Fundão, Rio de Janeiro, RJ, CEP 21941-902, Brasil.

Trepadeiras volúveis, sem gavinhas, suculentas, herbáceas ou ocasionalmente sufruticosas. **Caule** suculento, herbáceo ou lignificado, às vezes produzindo tubérculos aéreos e/ou subterrâneos. **Folhas** simples, alterno-espiraladas, pecioladas; sem estípulas. **Inflorescências** axilares ou terminais, espigas, racemos, panículas ou dicásios. **Flores** sésseis ou pediceladas, actinomorfas com exceção do cálice, bissexuais ou raramente funcionalmente unisexuais, casmógamas ou cleistógamas, subtendidas por 2 bractéolas; sépalas 2, valvares, opostas, alternas com as bractéolas, petaloïdes, persistentes e acrecenta nos frutos, livres a parcialmente conatas; pétalas 5, imbricadas, patentes ou eretas, persistentes e levemente acrecenta nos frutos; estames 5, epipétalos, conatos na base ou até 3/4 do comprimento, anteras dorsifixas, bitempas, deiscência rimosa, extrorsa; ovário súpero, gamocarpelar, unilocular, uniovulado, placenta basal, estilete 1-3, inteiro a trífido até próximo à base, estigma linear a capitado ou trilobado. **Fruto** aquênio, indeísciente, perianto persistente envolvendo sua base ou totalmente. **Sementes** com a testa membranosa.

Basellaceae é uma família de distribuição tropical e subtropical, tendo como centro de diversidade a região andina sul americana (Sperling & Bittrich 1993; Eriksson 2007). Compreende quatro gêneros e 19 espécies (Eriksson 2007) dos quais apenas *Anredera* Juss. é nativo do Brasil, sendo representado por duas espécies (Pellegrini & Sakuragui 2014). O gênero *Basella* L. é de origem africana (Sperling 1987; Eriksson 2007) e ocorre no Brasil apenas como subespontâneo ou como cultivado (Pellegrini & Sakuragui 2014).

A família apresenta grande valor alimentício e medicinal, com várias espécies cultivadas para esses fins: bertalha-verdadeira, olluco e folha-gorda [i.e. *Basella alba* L., *Ullucus tuberosus* Caldas e *Anredera cordifolia* (Ten.) Steenis, respectivamente]. No estado do Espírito Santo a família é representada pelo gênero *Anredera*.

1. *Anredera* Juss., nom. cons.

Trepadeiras suculentas, ocasionalmente sufruticosas. **Caule** glabro, suculento ou lignificado, liso ou rugoso, às vezes produzindo tubérculos aéreos. **Folhas** carnosas a membranáceas. **Inflorescências** axilares ou terminais, racemos ou panículas, pedúnculo delgado, não-carnoso, bractéolas conatas. **Flores** pediceladas, casmógamas, bissexuais, raramente funcionalmente unissexuais, perfumadas; estames reflexos em botão; estilete 1, inteiro a trífido até próximo à base, estigma linear a capitado ou trilobado. **Aquênia** envolto na base a completamente envolto pelo perianto persistente, membranáceo a paleáceo.

Anredera é o maior gênero da família, compreendendo 12 espécies. Exclusivamente Neotropical, é distribuído desde o sul dos Estados Unidos, passando pelo Caribe, até a Argentina e o Uruguai. Tem como centro de diversidade a região andina da América do Sul. *Anredera* pode ser facilmente diferenciada de *Basella* pelas inflorescências com raques

não-carnosas (vs. carnosas em *Basella*), bractéolas conatas (vs. livres), flores pediceladas e perfumadas (vs. sésseis e inodoras) e pelo pólen esférico e espinhoso (vs. cuboide a subcuboide e reticulado). No estado do Espírito Santo está representado por duas espécies.

Running title: Pontederiaceae in Vellozo's *Flora fluminensis*

Abstract- Notes on the Pontederiaceae names described in Vellozo's *Flora fluminensis*

The names of Pontederiaceae described by Vellozo in his *Flora fluminensis* are here revised, with an orthographical correction, two lectotypes and one epitype designated.

Key words

Aquatic flora, Commelinaceae, *Eichhornia*, *Heteranthera*, Rio de Janeiro

Resumo- Notas nos nomes de Pontederiaceae descritos por Vellozo na *Flora fluminensis*

No presente trabalho são revisados os nomes de Pontederiaceae publicados por Vellozo na *Flora fluminensis*, com uma correção ortográfica, dois lectótipos e um epítipo designados.

Palavras-chave

Commelinaceae, *Eichhornia*, *Heteranthera*, plantas aquáticas, Rio de Janeiro

Introduction

Vellozo's *Flora fluminensis* is a monumental work and the first one edited by a Brazilian botanist on our country's flora (Cervi & Rodrigues 2010). With funding of the Portuguese Empire, *Flora fluminensis* was a relevant part of the "Portuguese Philosophical Travels" that took place during the XVIII century. This Empire conducted several scientific expeditions across its world-wide domains with two campaigns in the Brazilian territory, with one of them being coordinated by Friar José Mariano da Conceição Vellozo (Damasceno 1977; Pataca 2011).

Flora fluminensis has been widely neglected since its publication due its historically difficult access and tortuous publishing history. It is also worth mentioning that at the time of its publication Vellozo's work was considered non-scientific, thus being highly depreciated by the academic community (Borgmeier 1961; Carauta 1969, 1973; Valle 1985). Combining this context with the general downgrading of taxonomy by the academic community, many plant groups lack recent floristic and taxonomic treatments (Funk 2006). This is also true for most aquatic plant families (Paz & Bove 2007), and Pontederiaceae is no exception. The group has been extensively studied under its reproductive and evolutionary aspects, but possesses just few papers recorded on taxonomy, especially dealing with their poorly resolved generic limits (Graham *et al.* 1998; Gomes 2000; Ness *et al.* 2011). For these reasons, little attention was ever given to the names of Pontederiaceae published by Vellozo (1829). These names were only featured in two national floras (Horn 1987a, 1987b), but completely out of the context of the Rio de Janeiro state flora or of a nomenclatural revision. This paper is part of a series dealing with the nomenclatural problems of the Commelinaceae names in Vellozo's *Flora fluminensis* (Aona-Pinheiro *et al.* 2014; Pellegrini *et al.* 2015; Pellegrini & Forzza *in press*; Pellegrini & Carvalho *in press*).

Original specimens and Typification

The original specimens collected by Vellozo were sent to the Museu Real de Lisboa between 1797 and 1798 (Hamy 1908; Borgmeier 1937). In addition to the specimens Vellozo placed in Lisboa, Hamy (1908) referred to 246 Vellozo specimens arranged in two separate batches (117 and 129 specimens) that were stated to have arrived in Portugal, with the first batch (consisting of 117 specimens) being sent to Paris (Bocage, 1862). Nevertheless, those specimens were expropriated during the Napoleonic invasion of Portugal in 1808 and nothing is known about the current whereabouts of Vellozo's original collection (Lima 1995; Cervi & Rodrigues 2010; Pastore 2013). Thus, making the iconographies of *Flora fluminensis* the best option for lectotypes and reviewing the described taxa (Carauta 1969; Mello Filho 1975; Cervi & Rodrigues 2010; Pellegrini *et al.* 2015).

Considering the abovementioned scenario, the names of Pontederiaceae described by Vellozo are here revised, with two lectotypes and an orthographical correction. An epitype was designated when the original plate was insufficient to apply a name to the given species with certainty. The species are presented here in the same order as that of Vellozo's *Flora fluminensis*.

Taxonomy

1. *Heteranthera reniformis* Ruiz & Pavón, Fl. Peruv. 1: 43, pl. LXXI. 1798.

Buchosia aquatica Vellozo, Fl. Flumin.: 33. 1829. **Lectotype (designated here):** [illustration] Original plate on parchment of “*Flora fluminensis*” in the Manuscript Section of the Biblioteca Nacional of Rio de Janeiro [mss1095062_084] and later published by Vellozo (1831. Fl. Flumin. Icon. 1: t. 80). **Epitype (designated here):** BRAZIL. Rio de Janeiro: Rio de Janeiro, entre o

Leblon e a Gávea, fl., 1942, *Dionisio s.n.* (2 ex RB 57561!). — For an image of the lectotype, see Fig. 1A-B; for an image of the epitype, see Fig. 2.

Nomenclatural notes: According to the *Code* (McNeill *et al.* 2012, Art. 60.1) the name *Buch’osia* consists of an orthographical error, which under the *Code* (McNeill *et al.* 2012, Art. 60.10) should be corrected by the suppression of the apostrophe. Although this is a situation of automatic correction, the wrong spelling is still used in scientific publications (Castellanos 1959; Horn 1985, 1987b). Nevertheless, since publications regarding the Pontederiaceae and Vellozo names have been few in the past years, this name has been long forgotten. Thus it is formalized here that the correct name for the genus is *Buchosia*, over the originally spelled *Buch’osia*.

Horn (1987a, 1987b) was the first to publish as *Buchosia aquatica* a synonym of *H. reniformis*, since Horn (1985) represents his unpublished Ph.D. thesis, and by means of the *Code* is not considered validly published (McNeill *et al.* 2012, Art. 29.1). The same is valid for all nomenclatural and taxonomical decisions proposed by the author at this time. Despite publishing the new synonym, Horn (1987a, 1987b) failed to lectotypify Vellozo’s name in both publications, since he never cited Vellozo’s plate. Thus, a lectotype is needed for the proper application of this name, being here designated.

Taxonomical notes: Despite *Buchosia* being considered a synonym of *Heteranthera* by Horn (1987a, 1987b), there does not seem to be an agreement over the application of *B. aquatica*, since it is often disregarded or missing in databases (e.g. eMonocot; The Plant List), being cited only in Tropicos.org. After carefully examining the original plate and description of *B. aquatica* it became clear that there are significant differences between the plant described and illustrated by Vellozo (1829, 1831) to the any known species of the genus *Heteranthera*, with respect to reproductive characters. Vellozo’s description for *Buchosia* mentions a 4-locular gynoecium and 4-valved capsules that are unknown for Pontederiaceae

(the fruit can be a 3-valved capsule or an achene, depending on the genus). These features can be also seen in the plate for *Buchosia aquatica* (Vellozo 1831, v. 1: t. 80; Fig. 1B). The plate also depicts a multibracteate inflorescence, with bracts of the same size as or bigger than the flowers, actinomorphic flowers and glabrous androecium (Fig. 1A-B). In contrast, *H. reniformis* is known to possess inflorescences subtended by a single bract, zygomorphic flowers and barbate stamens (Horn 1985). Nevertheless, many important vegetative, inflorescence and ecological features match perfectly to those of *H. reniformis*, such as the creeping and amphibious habit, reniform leaf blades with obtuse apex and all flowers opening at the same time (Horn 1985, 1987a, 1987b; Fig. 1A & E), leaving no doubt that it should be considered a synonym of the later.

The incongruence between *B. aquatica* and *H. reniformis* suggests that significant characters were wrongly portrayed for the plant in question. Thus, its lectotype is demonstrably ambiguous and cannot be critically identified for purposes of the precise application of the name. Thus, I apply Article 9.8 of the *Code* (McNeil *et al.*, 2012), and the selection of an epitype for *B. aquatica* serves to fix the application of this name in accordance with its current usage.

2. *Eichhornia azurea* (Sw.) Kunth, Enum. Pl. 4: 129. 1843.

Pontederia aquatica Vellozo, Fl. Flumin.: 144. 1829. \equiv *Eichhornia aquatica* (Vell.) Schltdl., Abh. Naturf. Ges. Halle 6: 177. 1862. **Lectotype (designated here):** [illustration] Original plate on parchment of “*Flora fluminensis*” in the Manuscript Section of the Biblioteca Nacional of Rio de Janeiro [mss1198652_168] and later published by Vellozo (1831. Fl. Flumin. Icon. 3: t. 164). — For an image of the lectotype, see Fig. 1C-D.

Nomenclatural notes: In the same way as above mentioned, Horn (1987a, 1987b) was the first to consider *Pontederia aquatica* a synonym of *E. azurea*. Nevertheless, he also failed to lectotypify Vellozo's name in both publications. Thus, a lectotype is here designated.

Taxonomical notes: *Eichhornia azurea* (Fig. 1F) is morphologically similar to *E. heterosperma* Alexander (Fig. 1G), being differentiated from the latter by its monomorphic seeds, puberulous stamens, fimbriate corolla margins and median-superior lobe of the corolla with a yellow spot [vs. dimorphic seeds, glabrous stamens, entire corolla margins and median-superior lobe of the corolla without a yellow spot] (Alexander 1939; Pellegrini pers. obs.). Besides that, only *E. azurea*, *E. crassipes* (Mart.) Solms and *E. diversifolia* (Vahl) Urb. are known to occur in the state of Rio de Janeiro (Amaral *et al.* 2015).

Vellozo's plate depicts perfectly the growth form, leaf and flower morphology characteristic to *E. azurea*, with only the stamens being mistakenly illustrated as glabrous (Fig. 1C-D). This is probably due to the fact that Vellozo's plates, especially the details, were mainly drawn based on dried specimens (H.C. Lima, *pers. comm.*). The description (Vellozo 1829) is impressively detailed when compared with the descriptions presented by botanists contemporary to him (such as Linnaeus), since he describes morphological, ecological and phenological aspects of this species. Thus, that being said, *P. aquatica* should be treated as a synonym of *E. azurea*, with no need to designate an epitype.

Acknowledgments

The author would like to thank CAPES (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior) for his M.Sc. scholarship. The author would also like to thank Luana Silva Braucks Calazans and Fernanda Santos-Silva for suggestions on an early version of the manuscript, RB staff for the photo of *Buchosia aquatica*'s epitype, André Cardoso, Martin

Acosta and Herison Medeiros for the pictures of *Eichhornia azurea* and *E. heterosperma*, respectively. The author would also like to thank Rafael Felipe de Almeida for suggestions on the manuscript and help with the edition of the plates, and three anonymous reviewers for valuable additions on the manuscript.

RESUMO: O presente estudo é uma contribuição ao projeto “Flora do Parque Nacional da Restinga de Jurubatiba, Rio de Janeiro, Brasil”. A família Commelinaceae encontra-se representada na área por três gêneros e seis espécies: *Commelina benghalensis* L., *C. erecta* L., *Dichorisandra hexandra* (Aubl.) Kuntze ex Hand.-Mazz., *D. procera* Mart. ex Schultes f., *D. thyrsiflora* Mikan e *Floscopia glabrata* (Kunth) Hassk. São aqui apresentadas descrições, ilustrações, comentários sobre a fenologia e os habitats, e uma chave de identificação para as espécies.

Palavras-chave: Commelinaceae. Floresta Atlântica. Taxonomia. Rio de Janeiro.

ABSTRACT: The present work is a contribution to the project “The Flora of the Restinga de Jurubatiba National Park, Rio de Janeiro, Brazil”. The Commelinaceae is represented by three genera and six species in the park area: *Commelina benghalensis* L., *C. erecta* L., *Dichorisandra hexandra* (Aubl.) Kuntze ex Hand.-Mazz., *D. procera* Mart. ex Schultes f., *D. thyrsiflora* Mikan e *Floscopia glabrata* (Kunth) Hassk. Descriptions, illustrations, comments on the habitat, phenology of the species and an identification key are here presented.

Key words: Commelinaceae. Atlantic Rainforest. Taxonomy. Rio de Janeiro.

COMMELINACEAE Mirb.

Ervas anuais ou perenes, frequentemente suculentas, glabras a esparsamente pilosas, rizomatosas ou estoloníferas; raízes fibrosas, finas ou espessadas; caule simples ou ramificado. **Folhas** simples, alternas dísticas ou espiraladas; bainha fechada, glabra, pilosa a densamente pilosa; margem inteira, ciliada ou glabra. **Inflorescências** compostas por um ou vários cincinios, livres ou fusionados, subtendidos por brácteas foliosas ou espatáceas, terminal, axilar e/ou basal. **Flores** actinomorfas ou zigomorfas, unissexuadas ou bissexuadas, ocasionalmente cleistógamas; sépalas 3, geralmente subiguais, livres ou conatas; pétalas 3, geralmente deliquescentes, iguais a desiguais, livres a parcialmente conatas; estames (1–3–5–)6, às vezes 1–3 modificados em estaminódios, filetes livres a contatos, às vezes epipétalos, glabros ou pilosos, anteras com deiscência rimosa ou mais raramente poricida; ovário súpero, 2–3-locular, estilete simples. **Frutos** cápsula loculicida ou mais raramente baga, 2–3-valvar, raramente indeiscente. **Sementes** ariladas ou não, testa com superfície lisa, rugosa, reticulada a reticulada-foveolada, areolada a areolada-foveolada, embrioteca dorsal, lateral ou semi-lateral.

Família predominantemente pantropical, com aproximadamente 41 gêneros e 650 espécies (FADEN & HUNT, 1991; APG III, 2009), representada no Brasil por 14 gêneros e aproximadamente 79 espécies (AONA & PELLEGRINI, 2013). São plantas que ocorrem nos mais diversos ecossistemas, podendo ser encontradas desde locais com forte influência antrópica, restingas, cerrados, mangues, florestas tropicais e subtropicais, até regiões temperadas (AONA & PELLEGRINI, 2013; BARRETO, 1997; FADEN, 1998). Commelinaceae carece bastante de trabalhos florísticos e taxonômicos recentes, especialmente no Brasil (PELLEGRINI *et al.*, 2013). No PNRJ está representada por três gêneros e seis espécies.

CHAVE PARA IDENTIFICAÇÃO DOS TÁXONS

1. Inflorescências reduzidas a 1-2 cincinios, subtendidas por uma espata; estames 6, sendo 3 superiores modificados em estaminódios e 3 inferiores férteis.

2. Bainha com margem ereta, folhas ovadas a largo-ovadas; inflorescências com os 2 cincinios férteis; pétala inferior pigmentada, cuculada; semente com testa estriada-reticulada... 1. *Commelina benghalensis*

2'. Bainha com margem auriculada, folhas ovado-lanceoladas a lanceoladas; inflorescências com o cincino superior abortado, inferior fértil; pétala inferior hialina, involuta; semente com testa lisa... 2. *Commelina erecta*

1'. Inflorescências em tirso propriamente ditos, subtendidas por uma bráctea foliácea; estames 6, todos férteis.

3. Sépalas com tricomas glandulares; anteras com deiscência rimosa; ovário e cápsulas estipitados, 2-loculares; sementes não-ariladas, embrioteca lateral... 6. *Floscopia glabrata*

3'. Sépalas glabras ou com tricomas não-glandulares; anteras com deiscência poricida; ovário e cápsulas sésseis, 3-loculares; sementes ariladas, embrioteca dorsal.

4. Plantas escandentes; caule ramificado; estames voltados para o lado superior da flor, anteras creme com o ápice ou os sacos polínicos lilases a azulados; arilo alaranjado... 3. *Dichorisandra hexandra*

4'. Plantas eretas; caule não-ramificado; 4 estames voltados para o centro da flor, os 2 laterais inferiores voltados para o lado externo, anteras amarelas; arilo alvo a acinzentado.

5. Anteras deiscentes por dois poros apicais; frutos completamente creme a esverdeados... 4. *Dichorisandra procera*

5'. Anteras deiscentes por um único poro apical; creme a esverdeados, com o ápice atrovináceo... 5. *Dichorisandra thyrsiflora*

Commelina L.

O gênero *Commelina* apresenta ca. 170 espécies e é o maior gênero da família, apresentando distribuição predominantemente pantropical. (FADEN, 1998). No Brasil

ocorrem oito espécies que crescem nos mais diversos ambientes, sendo encontradas em todas as regiões e biomas brasileiros (AONA & PELLEGRINI, 2013). No PNRJ está representado por duas espécies.

1. *Commelina benghalensis* L. (Fig. 1, A–B)

Species Plantarum 1: 41. 1753.

Ervas ca. 30cm, terrestres; caule prostrado, ramificado. **Folhas** alternas dísticas, subpecioladas; bainha 1,1–1,6cm compr., margem ciliada, tricomas hialinos a castanhos; lâminas ovadas a largo-ovadas, 2,3–7,4×0,9–3,4cm, esparsamente setosas a glabras, tricomas alvos, margem às vezes repanda, base arredondada, ápice agudo. **Inflorescências** aparentemente terminais, subtendidas por uma espata, inflorescências cleistógamas subterrâneas às vezes presentes, 1–3 por ramo; séssil a subséssil, pedúnculo 1–2mm compr. Composta por 2 cincinatos, o superior 1–3-floro, exserto, o inferior 3–5-floro, inclusivo, curto-piloso; espata transversalmente rombóide, 1,8–2×1–1,2cm, hirsuta, tricomas hialinos, margem posterior conata, ápice obtuso. **Flores** zigomorfas, bissexuais ou masculinas; sépalas 3, alvo-azuladas, hialinas; sépala dorsal ovada-lanceolada, 2–3×1,5–2,5mm, ápice agudo, sépalas ventrais livres, ovadas, 3–3,5×1,5–2mm, ápice obtuso; pétalas 3, sendo 2 superiores, azuis, unguiculadas, limbo reniforme a sub-cordado, 6–7×5–6mm, ápices arredondados; 1 inferior, alvo-azulada, séssil, ovado-lanceolada, cuculada, ca. 3×3mm, ápice agudo; estaminódios 3, filetes alvo-azulados, 2–3mm compr., anteródios amarelos, cruciformes, ca. 1×0,5mm; estames 3, desiguais estames laterais, filetes azulados, 5–6mm compr., anteras alvo-azuladas, ovadas, ca. 1×0,8mm; estame central, filete azulado, ca. 5mm compr., antera amarela, sagitiforme, falcada, ca. 1,5×0,5mm; ovário alvo, globoso, glabro, liso, ca. 1×1mm, estilete 5,5–6mm compr., estigma capitado. **Cápsulas** deiscentes, pardacentas, elipsoides, glabras, 4–5×3–4mm. **Sementes** castanhas, elípticas a ovadas, ca. 2×1,5mm, testa estriada-reticulada, embrioteca lateral.

Material examinado: Mun. Macaé: Córrego de Ouro, Fazenda Vitória, Morro do Oratório, J.P.P.Carauta 1364 (RB, U); Lagoa de Cabiúnas (Jurubatiba), M.F.Arnaud 1 (RFA).

Commelina benghalensis pode ser encontrada em todos os estados brasileiros (AONA & PELLEGRINI, 2013), sendo especialmente comum em ambientes mais secos e/ou antropizados. É dificilmente encontrada em locais sombreados, tendo preferência por ambientes luminosos e expostos. Apesar de terem sido encontradas apenas duas coletas para essa espécie, em uma das etiquetas, a espécie é referida como “comum no local”. Essa falta de registros, provavelmente, se deve a similaridade entre as espécies do gênero e por serem comumente tratadas como ruderais. Isso acaba por tornar as coletas desse gênero, proporcionalmente, escassas em relação a sua comum ocorrência.

Foi encontrada próxima a Lagoa de Jurubatiba e na Fazenda Vitória, sendo provavelmente encontrada por toda a extensão do parque, nas regiões de restinga arbustiva aberta, especialmente no primeiro cordão arenoso. No PNRJ foi encontrada com flor nos meses de maio e abril.

2. *Commelina erecta* L. (Fig. 1, C–D)

Species Plantarum 1: 41. 1753.

Ervas ca. 80cm, terrestres; caule ereto ou apoiante, ramificado. **Folhas** alternas dísticas, sésseis; bainha 0,8–1,1cm compr., margem auriculada, ciliada, tricomas alvos; lâminas lanceoladas a ovado-lanceoladas, 2–9×0,5–2,5cm, glabras a setosas a vilosas, tricomas alvos, base arredondada a cuneada, ápice agudo a acuminado. **Inflorescências** aparentemente terminais, subtendidas por uma espata, 1–3–(4) por ramo; séssil a subséssil, pedúnculo 2–4mm compr. Composta por 2 cincinatos, o superior abortado e inconstípido ou ausente; o inferior 3–5-floro, exserto, curto-piloso; espata depresso-ovovada a sub-cordada, 2,2–2,4×1,3–1,7cm, hirsuta a setosa a glabra, tricomas hialinos, margem posterior conata, ápice agudo. **Flores** fortemente zigomorfas, bissexuais ou masculinas; sépalas 3, alvo-esverdeadas, hialinas; sépala dorsal ovada-lanceolada, ca. 3–4×2–3,5mm, ápice agudo; sépalas ventrais conatas, ovadas, 5–7×5–6mm, ápice obtuso; pétalas 3, 2 superiores, azuis, unguiculadas, limbo reniforme depresso-ovovado, 1–2×1–2,5cm, ápices arredondados; 1 inferior, alva, hialina, séssil, lanceolada, fortemente involuta, 3–4×1–1,5mm, ápice agudo; estaminódios 3, filetes alvos, 5–7mm compr., anteródios amarelos, cruciformes, 1,5–2×2–2,5mm; estames 3, desiguais;

estames laterais 2, filetes alvo-azulados, 7–8mm compr., anteras alvas, ovadas, 1,5–2×0,5–1mm; estame central 1, filete alvo, 6–7mm compr., antera amarela, sagitiforme, falcada, 2,5–3×1–2,5mm; ovário alvo, globoso, glabro, liso, 1–1,5×0,7–1mm, estilete 7–8mm compr., estigma trilobado. **Cápsulas** deiscentes, pardacentas, oblongas, glabras, 5–6×3–4mm. **Sementes** pardas, elípticas, 2–3×1–2mm, testa lisa, embrioteca lateral.

Material examinado: Mun. Carapebus: restinga aberta, formação de *Allagoptera arenaria* (guriri), T.Konno et al. 1174 (R); loc. cit., Projeto Carapebus, mata, R.Moura et al. 53 (R). Mun. Macaé: Praia de Cabiúnas, caminho para a Lagoa de Jurubatiba, J.Fontella et al. 4029 (R); loc.cit., Parque Nacional da Restinga de Jurubatiba, J.P.P.Carauta et al. 412 (R); Parque Nacional da Restinga de Jurubatiba, entre as Lagoas Comprida e Carapebus, A.J. Castelo 173 (RB). Mun. Quissamã: restinga aberta, M.C.Oliveira et al. 761 (R).

Commelina erecta apresenta ampla distribuição geográfica e também no Brasil, ocorrendo em todos os estados brasileiros e em uma grande variedade de ecossistemas, como ambientes palustres, restingas, Cerrado, Caatinga, Floresta Atlântica, Floresta Amazônica e áreas antropizadas (AONA & PELLEGRINI, 2013). Na medicina popular é empregada no tratamento de diabetes, reumatismo, pressão alta e enfermidades nos olhos, sendo conhecida vulgarmente como “trapoeraba” ou “erva-de-santa-luzia”. É facilmente encontrada por toda a extensão do parque, nas regiões de restinga arbustiva aberta, especialmente no primeiro cordão arenoso. Exemplares em floração e frutificação podem ser observados ao longo de todo o ano, mas com o pico da floração e frutificação ocorrendo durante os meses chuvosos.

Dichorisandra J.C.Mikan

Dichorisandra é um gênero neotropical que ocorre da América Central até a Argentina e possui ca. 54 espécies, muitas ainda novas para a ciência (AONA, 2008). No Brasil espécies de *Dichorisandra* podem ser encontradas em todos os estados brasileiros, apresentando maior concentração de espécies nos estados do Rio de Janeiro, Minas Gerais, Espírito Santo e Bahia. As espécies do gênero ocorrem preferencialmente em

floresta atlântica, mata de altitude, mata semi-decídua, floresta amazônica de terra firme e restinga litorânea (AONA & AMARAL, 2009).

3. *Dichorisandra hexandra* (Aubl.) Kuntze ex Hand.-Mazz. (Fig. 1, E–G)

Denkschr. Kaiserl. Akad. Wiss., Math.-Naturwiss. Kl. 79: 203. 1908.

Commelina hexandra Aubl.

Ervas trepadeiras, terrestres; caule apoiante, raro ereto, ramificado. **Folhas** alternas dísticas, sésseis a sub-pecioladas; bainha 1–1,7cm compr., margem ciliada, tricomas alvos a castanhos; lâminas lanceoladas a ovado-lanceoladas, 6,9–7,8×1,5–2,3cm, face abaxial com tricomas esparsos, caducos, mais abundantes na base, face adaxial glabra a com raros tricomas, principalmente na base, ou glabra com nervura central pilosa, tricomas alvos a castanhos, base arredondada a cuneada, ápice acuminado. **Inflorescências** em tirso, terminais. **Flores** zigomorfas devido à posição dos estames, bissexuais ou masculinas; sépalas 3, alvo-esverdeadas, elípticas a ovais, 7–7,6×3–3,5cm, livres, pilosas, ápice agudo; pétalas 3, roxas a roxo-azuladas, terço basal alvo, obovais-elípticas a largo-obovadas, 7–8,2×3–3,5mm; estames 6, subiguais, voltados para o lado superior da flor, filetes alvos, ca. 2mm compr., anteras creme, sacos polínicos ou ápices lilases a azulados, alongadas, 2–3×0,5–1mm, deiscentes por 2 poros apicais; ovário alvo-esverdeado, globoso, glabro, liso a levemente rugoso, ca. 2×2mm, estilete 3–3,5mm compr., estigma truncado. **Cápsulas** deiscentes, cremes a esverdeadas, ápice atro-vináceo, globosas, glabras, lisas a levemente rugosas, 5–6×5mm. **Sementes** cinzas a pretas, elípticas a ovais, ca. 4×3mm, testa rugosa, arilo alaranjado, embrioteca dorsal.

Material examinado: Mun. Macaé: Jurubatiba, margem da lagoa de Cabiúnas, J.P.P. Carauta et al. 7412 (R).

Material adicional: Mun. Cabo Frio: Morro do Mico, próximo ao Bairro Jacaré, C.Farney 4556 (RB). Sem município definido: Estrada para Angra dos Reis, D.Sucre 10676 (RB).

Dichorisandra hexandra é a espécie com mais a ampla distribuição dentro do gênero. Ela ocorre na Argentina, Bolívia, Colômbia, Costa Rica, El Salvador, Guiana Francesa, Guatemala, Panamá, Paraguai, Peru, Suriname, Venezuela e no Brasil está presente em todas as regiões (BARRETO 1997, AONA & PELLEGRINI 2013). Ocorre, preferencialmente, em Floresta Ombrófila Densa Atlântica, em Floresta Estacional Semidecidual e na Floresta Ombrófila Densa Amazônica (AONA, 2008), sendo pouco frequente em matas de restinga. Pode ser encontrada em flor e fruto durante todo o ano.

4. *Dichorisandra procera* Mart. ex Schultes f. (Fig. 1, H–J)
in Schultes & Schultes f., Syst. veg. 7 (2): 1187. 1830.

Ervas até ca. 1,5m alt., terrestres; caule ereto, não ramificado ou ramificado na metade superior. **Folhas** alternas espiraladas, sésseis a sub-pecioladas; bainha 1,0–2,6cm compr., margem glabra a ciliada, tricomas castanhos; lâminas elípticas a lanceoladas, 10,6–25,1×2,3–6cm, glabras, raro com esparsos tricomas na base, base cuneada, margem glabra, ápice acuminado. **Inflorescências** em tirso, terminais. **Flores** zigomorfas devido à posição dos estames, bissexuais ou masculinas; sépalas 3, arroxeadas, elípticas a obovais, cculadas, 8×5mm, livres, glabras; pétalas 3, roxas a roxo-azuladas, terço basal alvo, obovadas a romboides, 8–10×5–7mm; estames 6, desiguais, 4 estames voltados para o centro da flor, os 2 laterais inferiores voltados para o lado externo, filetes alvos, 1–2mm compr., anteras amarelas, alongadas, 3–4×2mm, deiscentes por 2 poros apicais; ovário alvo a esverdeado, globoso, glabro, liso, ca. 2×2mm, estilete ca. 4mm compr., estigma truncado. **Cápsulas** deiscentes, creme a esverdeadas, globosas, glabras, lisas, ca. 1,5×1,5mm. **Sementes** cinzas a pretas, largo-elípticas a ovadas, 3–4×3mm, testa rugosa, arilo branco a acinzentado, embrioteca dorsal.

Material examinado: Mun. Macaé: Carapebus, Fazenda São Lázaro, restinga, vegetação fechada, próxima de pastagem, lado esquerdo da estrada, *L.C.Giordano et al. 1608* (RB); Restinga de Cabiúnas, mata de restinga, *D.Araújo & N.C.Maciel 4341* (GUA). Mun. Quissamã: Estrada para Barra do Furado, ca. 3km de Quissamã, *D.Zappi 393 et al.* (UEC).

Material adicional: RIO DE JANEIRO. Mun. Parati: Ponta do Algodão (Ponta Lava), Ilha dos Cocos, mata secundária, APA Cairuçu, *L.C. Giordano et al.* 1099 (RB, UFP).

Espécie endêmica do Brasil, com distribuição restrita aos estados de Alagoas, Bahia, Espírito Santo, Rio de Janeiro, Minas Gerais e Pernambuco (AONA & PELLEGRINI, 2013). É característica das formações de restinga arbórea e Floresta Ombrófila Densa de Terras Baixas (AONA, 2008). Apesar disso, a espécie é pouco comum no estado do Rio de Janeiro.

Dichorisandra procera foi muitas vezes confundida com *D. thyrsiflora* devido ao seu porte, disposição dos estames e pela ausência de pilosidade nas folhas. Apesar disso, difere da mesma por apresentar anteras deiscentes por dois poros apicais, enquanto que *D. thyrsiflora* apresenta anteras deiscentes por um único poro apical (AONA, 2008). Além disso, *D. procera* apresenta frutos completamente creme a esverdeados, enquanto *D. thyrsiflora* apresenta frutos creme a esverdeados com o ápice atro-vináceo.

5. *Dichorisandra thyrsiflora* J.C.Mikan (Fig. 1, K–L)

Delectus Florae et Faunae Brasiliensis, t. 3. 1820.

Ervas até ca. 2m alt., terrestres; caule ereto, não ramificado ou ramificado na metade superior. **Folhas** alternas espiraladas, sésseis a sub-pecioladas; bainha 1,2–3,6cm compr., margem ciliada, tricomias alvos a castanho-claros; lâminas lanceoladas a ovado-lanceoladas, 9–23,8×1,5–8,8cm, glabras, base cuneada, ápice agudo. **Inflorescências** em tirmos, terminais. **Flores** zigomorfas devido à posição dos estames, bissexuais ou masculinas; sépalas 3, arroxeadas, ovada-elípticas a elípticas, cuculadas, 7–9×3,5–5mm, livres, glabras a curto-pilosas no terço basal; pétalas 3, roxas a roxo-azuladas, terço basal alvo, obovadas a romboides, 0,9–1,5×0,8–1,5cm; estames 6, desiguais, 4 estames voltados para o centro da flor, os 2 laterais inferiores voltados para o lado externo, filetes alvos, 2–5mm compr., anteras amarelas, alongadas, 4–6×1–2mm, deiscentes por 1 poro apical; ovário alvo a alvo-esverdeado, globoso, glabro, liso, 2–2,5×1–2mm, estilete 2–4mm compr., estigma truncado. **Cápsulas** deiscentes, creme, ápice atro-purpúreo, globosas, glabras, lisas, 1,4–1,6×1,2–1,5cm. **Sementes** cinzas a pretas,

elípticas a reniformes, 4–5×3–4mm, testa rugosa, arilo branco a acinzentado, embrioteca dorsal.

Material examinado: Mun. Carapebus: mata em depressão próxima à estrada para a praia, *A.Costa et al.* 848 (R); orla da mata inundada, *J.Fontella et al.* 4016 (R); Fazenda São Lázaro, *J.Fontella et al.* 4134 (R); Praia de Carapebus, entre Lagoa Paulista e Lagoa de Carapebus, *C.P.R.Batista et al.* 32 (R); mata de restinga, *A.S.Oliveira et al.* 3807 (R); mata, *R.Moura et al.* 52 (R); Restinga de Carapebus, 2km da sede da Fazenda São Lázaro em direção a praia, *P.C.A.Fevereiro & M.G.Santos* 27 (RB, UFF); Restinga de Carapebus, Fazenda São Lázaro, *M.G.Santos et al.* 227 (RB, UFF); Restinga de Carapebus, Fazenda São Lázaro, *J.M.A.Braga et al.* 1172 (RB); Fazenda São Lázaro, *L.C.Giordano* 1608 (RB); Fazenda São Lázaro, *M.G.Bovini* 965 (RB). Mun. Macaé: Pico do Frade de Macaé, *G.Martinelli* 9112 et al. (RB); Restinga de Carapebus, *D.Araújo* 3740 et al. (GUA); Restinga de Carapebus, *D.Araújo & N.C.Macie* 3790 (GUA); Próximo a Lagoa de Carapebus, na orla arbórea em lugar úmido, *D.Araújo & N.Crud* 3586 (GUA); Airis, Fazenda Cachoeira, *J.P.P.Carauta* 1257 (GUA); Forte Marechal Hermes, restinga em morrete a beira mar, *R.Melo-Silva & J.R.Pirani* 857 (RB, SPF, NY). Mun. Quissamã: ao longo da estrada RJ-106, sentido Barra do Furado, *J.P. Fontella et al.* 3540 (R); restinga aberta, *I.M.Silva et al.* 765 (R); Machado, mata à beira da estrada, local brejoso, *I.M.Silva et al.* 921 (R); nascente da Lagoa Preta, restinga aberta, *I.M.Silva et al.* 772 (R); orla da mata, *M.C.Oliveira et al.* 819 (R); Imbiu, mata de restinga, *M.C.Oliveira et al.* 1178 (R); dentro da mata, em local úmido, *I.M.Silva et al.* 942 (R); cerca de 500m da praia do Visgueiro, *I.M.Silva et al.* 968 (R).

Dichorisandra thyrsiflora é uma espécie endêmica do Brasil, ocorrendo exclusivamente nos estados do Rio de Janeiro, Minas Gerais e Bahia (AONA & PELLEGRINI, 2013). Apesar disso, devido a sua grande beleza, é encontrada em diversos estados brasileiros e países ao redor do mundo como planta ornamental (AONA, 2008). Na medicina popular é empregada no tratamento de problemas renais e urinários. É conhecida vulgarmente como “cana-de-macaco”, “gengibre-azul” e “cana-do-brejo”. É uma espécie bastante comum e característica de restingas e outras vegetações de influência marítima, mas também pode ser encontrada em regiões serranas, tendo de maneira geral preferência

por ambientes mais sombreados e úmidos (AONA, 2008). Pode ser encontrada em floração em frutificação ao longo de todo o ano.

Floscopia Lour.

Gênero pantropical, com ca. 20 espécies (FADEN, 1998). No Brasil é representado por quatro espécies, três exclusivas do domínio Amazônia e *F. glabrata*, que ocorre em todas as regiões brasileiras (AONA & PELLEGRINI, 2013). As espécies desse gênero são encontradas em vegetação aberta ou fechada, mas sempre associado a corpos d'água ou em locais bastante úmidos.

6. *Floscopia glabrata* (Kunth) Hassk. (Fig. 1, M–N)

Commelinaceae Indicae 166. 1870.

Dithyrocarpus glabratus Kunth

Ervas perenes, até 1m alt., palustres a aquáticas emergentes. **Caule** ereto, pouco a não ramificado, glabros a densamente pilosos, tricomas curtos, alvos. **Folhas** alternodísticas, sésseis; bainhas 0,5–2,4cm compr., glabras a densamente hirsutas, margem ciliada, tricomas longos, alvos; lâminas linear-lanceoladas a ovado-lanceoladas, 2,5–15×0,5–2,5cm, verdes, ápice agudo a acuminado, margem ciliada, glabra a hirsutas, tricomas alvos, base cuneada a arredondada. **Inflorescências** em tirso, terminais e axilares, pedunculadas, congestas nos ápices dos ramos, cincinatos 8–20-floros. **Flores** fortemente zigomórficas, bissexuais; sépalas levemente côncavas, elípticas a ovadas, 2–3×1–1,5mm, sub-iguais, róseas a lilases, externamente com tricomas glandulares; pétalas elíptico-obovadas a largo-elípticas, a inferior mais estreita e levemente involuta ou cículada, ca. 2×1mm, alvas a róseas a lilases, margem inteira, ápice agudo; estames superiores 3, menores, filetes ca. 1,5mm compr., róseos a lilases, glabros, livres, anteras ca. 0,4×0,3mm, amarelas, rimosas, sacos polínicos ovados a elípticos, levemente curvos, conectivo expandido, elíptico, estames inferiores 3, maiores, filetes ca. 2mm compr., róseos a lilases, glabros, livres a conatos na base, anteras ca. 0,4×0,3mm, amarelas, rimosas, saco polínico ovados a elípticos, conectivo não-expandido; ovário ovóide, estipitado, ca. 0,4–0,5×0,3–0,4mm, róseo, glabro, liso, estilete 7–8mm compr., curvo, estigma truncado, papiloso. **Cápsulas** obcordadas, levemente achatadas

lateralmente, estipitadas, 1–2×1,5–3mm, pardacentas a acinzentadas, sépalas persistentes. **Sementes** cinzas, globosas, ca. 1,2×1mm, testa costada a tuberculada, embrioteca lateral.

Material examinado: Mun. Macaé: estrada para a Lagoa Comprida, à margem do canal, *D.Araújo & N. Crud 5028 (GUA)*.

Material adicional: RIO DE JANEIRO. Mun. Santa Maria Madalena: Tamanduá, *E. Pereira 1261 (IPA, RB, UB)*. Mun. Silva Jardim: Reserva Biológica de Poço das Antas, região próxima a BR-101, área do aceiro *C.M. Vieira 914 (RB)*.

Floscopia glabrata apresenta ampla distribuição no Brasil, desde a Região Norte até a Região Sul. Ocorre geralmente em locais muito úmidos, às margens de córregos e rios, em igapós e até mesmo dentro da água (AONA & PELLEGRINI, 2013). A floração da espécie, bem como a frutificação, ocorre em praticamente todos os meses do ano.
